*Form Approved
OMB No. 0704-0188*

The public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing the burden, to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.
PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.

| 14. ABSTRACT The objective of this project was to demonstrate a family of technologies adapted from the oceanographic and environmental arenas that could significantly improve our ability to address contaminant source exposure, transport and fate challenges at Department of Defense (DoD) coastal site in a relatively simple and cost effective way. Through the integration of these technologies, our goal was to develop and demonstrate a spectrum of new capabilities. | | | | | |

| EXECUTIVE SUMMARY | xxiii |
| Objective..... | xxiii |
| Description of the Technology | xxiii |
| Performance Objectives and Results | xxiv |
| Performance Evaluation | xxix |
| Cost Analysis..... | xxx |
| Implementation Status | xxx |
| 1 INTRODUCTION..... | 1 |
| 1.1 Background | 1 |
| 1.2 Objectives of the Demonstration..... | 3 |
| 1.3 Regulatory Drivers | 4 |
| 2 TECHNOLOGY..... | 9 |
| 2.1 Technology Description and Development..... | 9 |
| 2.1.1 Drifting Exposure System..... | 9 |
| 2.1.2 Drifting Particle Simulator..... | 17 |
| 2.1.3 Sediment Deposition Detector | 21 |
| 2.2 Advantages and Limitations of the Technology | 26 |
| 2.2.1 Drifting Exposure System..... | 26 |
| 2.2.2 Drifting Particle Simulator..... | 27 |
| 2.2.3 Sediment Deposition Detector | 28 |
| 3 PERFORMANCE OBJECTIVES..... | 29 |
| 3.1 Drifting Exposure System | 29 |
| 3.2 Drifting Particle Simulator | 29 |
| 3.3 Sediment Deposition Detector | 30 |
| 3.4 Quantitative Performance Objectives – Drifting Exposure System..... | 33 |
| 3.4.1 Tracking Accuracy..... | 33 |
| 3.4.2 Communications reliability..... | 33 |
| 3.4.3 Water sampler operation..... | 33 |
| 3.4.4 System survivability..... | 34 |
| 3.5 Qualitative Performance Objectives – Drifting Exposure System..... | 34 |
| 3.5.1 Surface plume tracking effectiveness | 34 |

| | | |
|-------|---|----|
| 3.6 | Quantitative Performance Objectives – Drifting Particle Simulator System..... | 35 |
| 3.6.1 | Tracking Accuracy..... | 35 |
| 3.6.2 | Communications reliability..... | 35 |
| 3.6.3 | Settling Rate..... | 35 |
| 3.6.4 | System survivability..... | 35 |
| 3.7 | Qualitative Performance Objectives – Drifting Particle Simulator System..... | 36 |
| 3.7.1 | Particle plume tracking effectiveness | 36 |
| 3.8 | Quantitative Performance Objectives – Sediment Deposition Detector | 36 |
| 3.8.1 | Deposition Detection Sensitivity | 36 |
| 3.8.2 | Measurement Reliability..... | 36 |
| 3.8.3 | System survivability..... | 37 |
| 3.9 | Qualitative Performance Objectives – Sediment Deposition Detector | 37 |
| 3.9.1 | Ease of installation and retrieval..... | 37 |
| 4 | SITE DESCRIPTION | 39 |
| 4.1 | Demonstration 1: Naval Base San Diego – Paleta Creek..... | 39 |
| 4.2 | Demonstration 2: Joint Base Pearl Harbor Hickam – Oscar Pier | 41 |
| 4.3 | Demonstration 3: Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area..... | 44 |
| 5 | TEST DESIGN..... | 47 |
| 5.1 | Conceptual Experimental Design..... | 47 |
| 5.1.1 | Field Demonstration 1: Naval Base San Diego – Paleta Creek | 47 |
| 5.1.2 | Field Demonstration 2: Joint Base Pearl Harbor Hickam – Oscar Pier | 47 |
| 5.1.3 | Field Demonstration 2: Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area | 48 |
| 5.2 | Baseline Characterization Activities | 52 |
| 5.2.1 | Naval Base San Diego – Paleta Creek | 52 |

Figure 87. Wind and tide conditions for the March 12-13, 2016 DPS survey event..... 160

Figure 88. DPS trajectories and tide conditions for DPS1-1, DPS3-1, and DPS4-1. Colors indicate the DPS depth in meters. Yellow circle is the release point. 161

Figure 89. DPS trajectories and tide conditions for DPS5-1, DPS6-1, and DPS7-1. Colors indicate the DPS depth in meters. Yellow circle is the release point. 162

Figure 90. DPS trajectories and tide conditions for DPS8-1, DPS9-1, and DPS10-1. Colors indicate the DPS depth in meters. Yellow circle is the release point. 163

Figure 91. DPS trajectories and tide conditions for DPS1-2, DPS4-2, and DPS5-2. Colors indicate the DPS depth in meters. Yellow circle is the release point. 164

Figure 92. DPS trajectories and tide conditions for DPS1-3, DPS7-2, and DPS9-2. Colors indicate the DPS depth in meters. Yellow circle is the release point. 165

Figure 93. DPS trajectories and tide conditions for DPS4-3 and DPS5-3. Colors indicate the DPS depth in meters. Yellow circle is the release point. 166

Figure 94. Complete DPS trajectory map showing individual trajectories for the 17 DPS units (colored lines) and bottom contact locations (green x's)..... 167

Figure 95. Deposition footprint with connectivity to the stormwater discharge outfall near Oscar Pier. The light shaded area indicates the area encompassed by the actual bottom contacts for the target 34 mm/min (silt) settling rate particles. The darker shaded area encompasses the trajectories and bottom contacts and is representative of the potential deposition of particles sinking at ≤ 34 mm/min (silts and sands). The green x's are the actual bottom contact locations. 168

Figure 96. Total travel distance and tide condition for each of the DPS units released during the Mar 12-13, 2016 Oscar Pier event. Shown in order of release from left to right. 169

Figure 97. Average speed and tide condition for each of the DPS units released during the Mar 12-13, 2016 Oscar Pier event. Shown in order of release from left to right. 170

Figure 98. Vertical profiles of DPS depth as a function of time. Labels are DPS unit and deployment numbers. Red circles indicate bottom contact times and depths. 171

Figure 99. Salinity data (psu) from the sensors onboard the DPS units during the Mar 12-13, 2016 event. 172

Figure 100. Temperature data ($^{\circ}\text{C}$) from the sensors onboard the DPS units during the Mar 12-13, 2016 event. 173

Figure 101. Location map for the SeDep systems in Pearl Harbor during the March 15 – April 26, 2016 event. 176

Figure 102. Tide and wind speed conditions during the SeDep deployment event in Pearl Harbor from March 15 – April 26, 2016 (Julian Day 74-116). 178

Figure 103. Cumulative precipitation and sediment deposition for the SeDep deployment event in Pearl Harbor from March 15 – April 26, 2016 (Julian Day 74-116). Vertical dotted lines indicate the two significant precipitation events during the deployment. Solid SeDep lines are for sensors that were placed to the north (further into the harbor) and dashed lines are for sensors that were near the outfall or to the south (further toward the harbor entrance). 179

Figure 104. Comparison of overall deposition rates measured by the sediment traps and the SeDep sensors. The inset plot shows a regression of the deposition rates measured by the two methods ($R^2 = 0.93$; Slope = 0.91). 181

Figure 105. Mercury concentrations in deposited sediments and deposition rates based on the SeDep sediment traps. 184

Figure 106. Copper concentrations in deposited sediments and deposition rates based on the SeDep sediment traps. 185

EXECUTIVE SUMMARY

Objective

The objective of this project was to demonstrate a family of technologies adapted from the oceanographic and environmental arenas that could significantly improve our ability to address contaminant source exposure, transport and fate challenges at Department of Defense (DoD) coastal site in a relatively simple and cost effective way. Through the integration of these technologies, our goal was to develop and demonstrate a spectrum of new capabilities. Our demonstration focused on three key products including:

- Drifting Exposure System (DrEx): Surface global positioning system (GPS) drifter with position data telemetry, composite sample collection and passive sampler capabilities for exposure characterization.
- Drifting Particle Simulator (DPS): GPS drifter with position data telemetry, buoyancy control, bottom detection, and passive sampling capability for measurement of depositional footprints and sampling of source related particles.
- Sediment Deposition Detector (SeDep): Sediment bed scour sensor with high resolution differential pressure sensor, shore cable or in situ data logging, and coupled sediment trap capabilities for simultaneous quantitative measurement of deposition rates and sampling of depositing particles.

We envision that these technologies will provide a broad new set of capabilities that are highly applicable to characterizing the exposure, transport and fate of stormwater contaminant sources.

Description of the Technology

Drifting Exposure System

The DrEx is a surface GPS drifter with position tracking and data telemetry, onboard sensors, composite sample collection and passive sampler capabilities for exposure characterization. It is based on their standard Davis/CODE (Coastal Ocean Dynamics Experiment) design but incorporates a new composite sampling capability. The combined system allows for both the tracking and sampling of surface plumes from stormwater and other discharges.

Drifting Particle Simulator

The DPS is based on an integration of the Pacific Gyre Microstar Lagrangian Drifter design with GPS tracking and Iridium satellite communications, and a high resolution depth-control underwater micro-winch. The DPS drifter tracks water currents at depths of 1 to 20 meters, and is equipped to accommodate a range of additional sensors. The system is configured with a spherical surface float housing the GPS and Iridium satellite communications, a “Holey Sock” subsurface drogue, and is supported by data archival, mapping, web access capabilities. The system is designed to house the underwater micro-winch along the central axis of the subsurface drogue, and maintain adequate drag to drogue ratios for water depths in the range of 1 – 20 meters. In combination with the underwater micro-winch, the system provides the ability to use these drifters to mimic the settling velocities of particles by automatically adjusting the depth of

subsurface drogue relative to the surface float, allowing for simulation of effective particle settling rates in ocean, river and lake currents.

Sediment Deposition Detector

The SeDep system consists of a standard United States Geological Service (USGS) Load-Cell Scour Sensor provided by Rickly Hydrological Corp. that was modified to incorporate a highly sensitive differential pressure sensor in place of the standard pair of absolute pressure sensors. The sensor weighs the sediment, water, and air above it and an accompanying pore-pressure sensor weighs the water and air above it. The difference between the two weights is the weight of the sediment overlying the sensor pair. With the new integration of the differential pressure sensor in place of the standard sensor pair, the depth limit of the system is increased by two orders of magnitude from 3.5 m, to 350 m, and the sensitivity is improved by about 2 orders of magnitude from 3 mm to about 0.05 mm. These improvements were critical to the application of the system for assessment of stormwater events and potential recontamination of the sediment bed. In addition, the standard unit required cables run to shore for monitoring, while the new system incorporates an onboard data logger that can be left at the site for extended periods. The SeDep incorporates a standard sediment trap to allow of collection and analysis of deposited sediments.

Performance Objectives and Results

Performance analysis focused on the ability of the systems to provide improved exposure, transport and fate assessment for stormwater sources in a cost effective manner. A key aspect of this performance was the ability to improve our understanding of the linkage between this ongoing sources and potential recontamination of sediment. This requires the ability to accurately track the trajectory of the plume and associated particle-bound contaminants, and establish reliable measures of event-based depositional footprints. Performance was measured against performance criteria established in the demonstration plan. Performance objectives for the three technologies are summarized in Table 4 and Table 5.

Drifting Exposure System

For the DrEx system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on tracking accuracy, communications reliability, water sampler performance, and system survivability. The primary qualitative performance object for the DrEx was that the drifters reliable track the surface plume of a stormwater discharge release.

Quantitative Performance Objective – Tracking Accuracy: GPS accuracy data and statistics were collected during field deployments at Paleta Creek in San Diego Bay. The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period provided that the SBAS differential system was active. Results based on the Trimble GeoXT GPS measurements showed 90th percentile differences of 4.9 m and 6.4 m for the Jan 5-6, 2016 event and Feb 1 event, respectively. Results from the BadElf global navigation satellite system (GNSS) GPS measurements showed 90th percentile differences ranging from 5.4-5.5 m for the Jan 5-6, 2016 event, and 5.0-5.6 m for the Feb 1, 2016 event. While these values and ranges generally slightly exceeded the performance objective, the objective was considered to be met because the results were generally both very consistent and also very close to the objective.

Quantitative Performance Objective – Communications reliability: Telemetry link data and statistics for the DrEx were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. Results for communications reliability were evaluated for each of the two survey events. During the Jan 5-6, 2016 event, communications reliability ranged from a low of 59% to a high of 94%, with an overall average of 81%. During the Feb 1, 2016 event, reliability ranged from 34% to 100% with an overall average of 77%. While these levels fall somewhat short of the performance goal, experience during the events indicated that the communications reliability was generally sufficient to provide adequate information on the locations of the drifters throughout the deployments, as well as providing accurate information on the location for the retrieval.

Quantitative Performance Objective – Water sampler operation: Water sampler operation data were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate reliable composite sample with total volume within 10% of the user specified target. Results for water sampler operations were evaluated for each of the two survey events. For the Jan 5-6, 2016 event, percent differences between the pump estimated volume and the measured volume ranged from 14% to 100% with an overall average of 41%. Large differences were primarily attributable to leaks that developed in the sampling bags after retrieval of the drifters. Considering only the units that were operational and had no leaks, the percent difference had an average of 14%. For the Feb 1, 2016 event, percent differences ranged from a low of 1% to a high of 91% with an overall average of 20%. Prior to this event, outer sleeves were added to protect and support the sampling bags. Only one sampling bag developed a leak during this event (DrEx 109). Eliminating this unit from the analysis, the average percent difference was found to be 12%. In general, for operational units with no leaks, the performance of the sampling system provided good agreement with the post-survey volume measurements within the range of about 12-14%. While this is slightly higher than the 10% target, it is still adequate to achieve the sampling requirements for the system.

Quantitative Performance Objective – System survivability: System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). Results for system survivability were evaluated for both survey events. For the Jan 5-6, 2016 event, no drifters were lost or sustained major damage. One drifter (109) failed due to a faulty mounting bracket that caused the magnetic switch to deactivate and shutdown the system. This only required a minor repair. For the Feb 1, 2016 event, no drifters were lost or sustained major damage. One drifter (112) lost its conductivity/temperature sensor. The same drifter also had some saltwater flooding to the pump housing for the water sampler. The total damage was estimated to be less than 25% of the drifter value. Overall, the performance objective for system survivability was met because no drifters were lost or sustained major damage.

Qualitative Performance Objectives – Surface plume tracking effectiveness: The goal for this qualitative performance objective was to demonstrate that the DrEx units generally tracked the stormwater plume based on the onboard salinity and temperature signature being consistent with

plume characteristics. For the Jan 5-6, 2016 event, we evaluated plume tracking based on the onboard sensors and vertical profiles collected along axial transects through the plume at three different time points during the storm. Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. Vertical profile transects also indicated that the drifters generally stayed within the plume. For the Feb 1, 2016 event, we evaluated plume tracking based on the onboard sensors and surface water mapping conducted at one time point during the storm event. Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. The surface water mapping transect also indicated that the drifters generally stayed within the plume. Overall, the performance evaluation for the surface plume tracking effectiveness indicated that the success criteria were met.

Drifting Particle Simulator

For the DPS system, we established a series of quantitative and qualitative performance objectives similar to the DrEx but adapted to the particle tracking capability of the system. Quantitative objectives focus on tracking accuracy, communications reliability, settling rate performance, and system survivability. The primary qualitative performance object for the DPS is that the drifters reliable track the particle plume of a stormwater discharge release.

Quantitative Performance Objectives – Tracking Accuracy: GPS accuracy data and statistics were collected during field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period. For the March 12-13, 2016 event at Oscar pier, a total of 62 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 3.4 m. For the October 28-29, 2016 event at Waiiau, a total of 28 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 4.8 m. The results indicate that the success criteria for the DPS tracking accuracy performance objective was met.

Quantitative Performance Objectives – Communications reliability: Telemetry link data and statistics for the DPS were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. For both DPS survey events, the communications reliability averaged 100%. Thus the success criteria for this performance objective was met.

Quantitative Performance Objectives – Settling Rate: Settling rate data were collected from the pressure sensor onboard the DPS units. The goal of this performance objective was to demonstrate accurate settling rates within 10% of target rate. The target settling rate for both survey events was 34 mm/min. For both events, the average percent difference from the target settling rate was less than 0.0%. Thus the success criteria for the settling rate performance objective was met.

Quantitative Performance Objectives – System survivability: System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). For the Mar 12-13, 2016 event, no DPS units were lost, and one DPS unit sustained major damage.

System survivability for this event was thus 90%. For the Oct 28-29, 2016 event, no drifters were lost or sustained major or minor damage. System survivability for this event was thus 100%. Overall, the performance objective for system survivability was met.

Qualitative Performance Objectives – Particle plume tracking effectiveness: Data on plume tracking was originally expected to be collected in the field when the DPS units were released during stormwater discharge events. However, the logistics of releasing the units during events proved to be difficult with limited storm events, long-distance travel to Pearl Harbor and obtaining permission for releases on short notice at the installations. As an alternative, we collected the DPS trajectory data during the field demonstrations in Pearl Harbor, and then compared those results to simulations from the available hydrodynamic model for releases at the same locations under the same conditions. The goal for this performance objective was to show that DPS units provide a qualitatively similar estimate of particle trajectories and deposition footprints as other available approaches. For the Mar 12-13, 2016 event, the two methods show good agreement, with the DPS bottom contacts generally falling within the areas where the model showed the majority of deposition associated with silt particle release from Oscar Pier. Similar results were found for the Oct 28-29 event. On the basis of these qualitatively similar results, we concluded that the success criteria for this performance objective was met.

Sediment Deposition Detector

For the SeDep system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on deposition detection sensitivity, measurement reliability, and system survivability. The primary qualitative performance object for the SeDep is that the system be reasonably easy to use in the field.

Quantitative Performance Objectives – Deposition Detection Sensitivity: The SeDep uses a precision differential pressure sensor to detect sediment deposition and scour. To quantitatively test the sensitivity of the system in the lab, SeDep units were submerged in a test tank and known weights were added to the pressure plate in the form of thin sheets of rubber. The goal for this performance objective was to demonstrate that the sensitivity of the SeDep was equivalent to <1 mm of sediment deposition. Testing of the original SeDep systems using the Omega sensors showed minimum detection limits (MDLs) for thickness ranging from 0.008 to 0.014 mm with an overall average of 0.012 mm. This level of detection sensitivity was well below the success criteria. However, the sensors were found to have two issues during longer deployments in the field. First, the sensors had a tendency to drift, requiring weight tests before and after the deployment and detrending of the field results. Second, the sensors were found to corrode and several units became inoperable shortly after the first long field deployment. Based on these findings, an improved sensor (Validyne) was identified, tested, and incorporated into the system. Time constraints on the project limited the full integration and application of these new sensors. However initial lab and field testing indicated that the primary issues with the original sensors were resolved. Overall, the success criteria for this performance objective was met.

Quantitative Performance Objectives – Measurement Reliability: The SeDep collects differential pressure data continuously at a rate of once every two seconds over periods of days to months. Data for measurement reliability were obtained from differential pressure data during the field deployments in Pearl Harbor. The goal for this performance objective was to demonstrate reliable pressure data collected >90% of the deployment period. Reliability ranged from 87% to 100% for the ten units, with an overall average of 97%. Reliability less than 100%

occurred for three units due to failure of the adhesive that was used to secure the pressure plate membrane. On the basis of these results, we concluded that the success criteria for the measurement reliability performance objective was met.

Quantitative Performance Objectives – System survivability: The SeDep units are designed to be deployed in harbor and coastal areas where exposure to harsh conditions is likely. System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). During and following the Pearl Harbor deployment, two issues occurred that impacted the system survivability performance. During the deployment period, the pressure plate membrane on three of the units (3, 7 and 10) failed, leading to a loss of pressure difference signal. This failure was considered minor damage because replacement of the membrane is a relatively small cost as a percentage of the entire system (about 10%). After recovery, the units were tested and post-survey weight calibrations were performed successfully. However, about 5 weeks after the recover, it was discovered that five of the pressure sensors (1, 3, 4, 6, and 9) had failed, apparently due to corrosion that had taken place inside of the sensing element. Based on these failures, combined with the sensor drift issue identified for the Omega sensors, we elected to replace the Omega sensors with an improved sensor from Validyne. To further reduce potential issues with corrosion, we also fully sealed the new sensors in polyurethane. Initial pier-side testing indicates that these improvements have successfully addressed the survivability and stability issues identified during the Pearl Harbor deployment, although long-term deployments are still needed to verify the robustness of the new configuration. Overall, the survivability success metric was not met; however, the issues that were identified have been addressed.

Qualitative Performance Objectives – Ease of installation and retrieval: The SeDep system provides a unique capability to monitor a continuous time series of sediment deposition at a fixed location while simultaneously capturing samples for subsequent physical and chemical analysis. A key aspect of the acceptance of the technology is that it be relatively easy to install and retrieve so that a reasonable number of samplers can be used to monitor the area of interest. Data to assess the ease of installation and retrieval was collected based on field logsheets and feedback from the field and dive teams. The goal for this performance objective was to demonstrate the ease of installation and retrieval for the SeDep system, and the ability to install or retrieve a typical system array within a reasonable time period of 1-2 days. The ease of installation and retrieval was evaluated during the Pearl Harbor demonstration. The divers reported that the deployments were straightforward and the only difficulties that were encountered were deployment into an area containing coral rubble mixed with sediment that made it difficult to properly embed the SeDep unit into the bottom. Retrieval of the systems was also uneventful. The overall retrieval rate was 10 stations in less than 3 hours for a retrieval rate of about 3.3 stations/hour. Overall, the success criteria for the ease of installation and retrieval performance objective was met.

Performance Evaluation

Drifting Exposure System: Performance for the DrEx system was evaluated during two demonstration events at the mouth of Paleta Creek at Naval Base San Diego (NBSD). The first was conducted during a relatively large storm event on Jan 5-6, 2016 with a cumulative rainfall of about 45 mm. The second was conducted during a smaller storm event on Feb 1, 2016 in the same area with cumulative rainfall of about 10 mm. In both cases, ten drifters were released into the first flush of the storm event to track the plume and collect samples during exposure periods that ranged from about 12 hours for the large event to about 6 hours for the small event. Overall, performance results from the DrEx demonstrations indicated that:

- The GPS tracking data from the DrEx systems provided a clear visualization of the area of the bay with connectivity to the stormwater plume, the spatial and time scale of the plume, the rate of movement of the plume, the rate of spreading of the plume, and the relationship to complex forcing from the stormwater and the tide.
- Sensor data from the DrEx units were very useful in evaluating the dynamics of the stormwater plume, the dilution of the plume over time, and the influence of other stormwater sources in the general vicinity.
- Composite samples from the events provided an effective means for characterizing exposure conditions within the first flush portion of the discharge plume from both a chemical and toxicological perspective.
- Differences in the dispersion, spatial scales, and exposure levels of the plumes were clearly discernable between the two events.
- The units stayed within the plume and recorded conditions that were consistent with the exposure that would be expected for the first-flush portion of the plume as it disperses into the receiving water.
- While still developmental, the passive sampler results indicated that there is potential for their application on these drifting exposure systems. The diffusive gradient in thin film (DGT) samplers are better suited to the application because the exposure time scale is more in line with the standard DGT method. The solid phase micro extraction (SPME) samplers have potential, but the application is not truly passive because it requires pumping, and more work is needed to better refine the method and improve the response time.

Drifting Particle Simulator: Performance of the DPS system was evaluated during two demonstration events in Pearl Harbor. The first event was conducted at the Oscar Pier site in Pearl Harbor during the period March 12-13, 2016. The second event was conducted at the Waiuu Generating Station site. The DPS survey at Waiuu was conducted during the period from October 28-29, 2016. During each event, DPS units were deployed at approximately hourly intervals throughout a full 24 hour tidal cycle. The DPS units were tracked until they made bottom contact, and the resulting bottom contact map was used to construct deposition footprints for each of the outfall sites where the demonstrations were performed. Overall, performance results from the DPS demonstrations indicated that:

The GPS tracking and bottom contact data collected using the DPS systems provided a clear visualization of the area of the harbor with connectivity to the outfall, the depth, spatial and time scales of the transport area, and the spatial location and size characteristics of the deposition footprint. These are all key aspects in understanding the complex nature and extent of the particle transport associated with discharge from a given outfall location.

- The DPS system can act as a platform for sensors to track background or storm event conditions during the trajectories of the drifters.
- The results compare favorably to model simulations for particle transport and settling performed for the same sites.

Sediment Deposition Detector: Performance of the SeDep system was evaluated during a single demonstration event in Pearl Harbor. The event was conducted at the Oscar Pier site in Pearl Harbor during the period March 12 – April 26 in conjunction with the DPS demonstration. Based on the DPS deposition footprint results from the Mar 12-13, 2016 event, ten SeDep units were deployed. The deployments were focused in the nearfield area of the footprint with an additional unit deployed further into the harbor and further out toward the entrance to characterize the far field areas of the footprint. Deposition data were collected continuously over the 42 day period of the deployment. The precipitation record shows that two moderate storm events and several smaller events took place during the deployment period, totaling about 13 mm. Overall, performance results from the SeDep demonstrations indicated that:

- The SeDep sensor systems provided a unique temporal quantification of cumulative sediment deposition under conditions that are representative of DoD harbors subject to stormwater and other sediment transport processes.
- The sediment traps that were collocated with the SeDep sensors provided an effective means of collecting deposited sediments, and the deposition rates were consistent with expectations regarding the typical rates in Pearl Harbor.
- In conjunction with the deposition data, the sediment trap and surface sediment chemistry were useful in evaluating the potential for recontamination at the deployment site. For the Pearl Harbor site, the results indicated that incoming sediment particles generally had lower contaminant concentrations than surface sediments, indicating that they should tend to improve conditions over time. However some chemicals including mercury and PCBs had particle input concentrations that still exceed their respective preliminary remediation goals (PRGs).
- Spatial distributions of trap and surface sediments suggest that the chemicals of concern may have different sources that are driving conditions at the site, with some chemicals showing gradients to the south (mercury and polychlorinated biphenyls [PCBs]), some showing gradients to the north (copper), and some being fairly evenly distributed off the outfall (lead).

Cost Analysis

The focus of these technology demonstrations was on the evaluation of new capabilities that expand the tool box for assessing stormwater and sediment recontamination beyond what is

currently available. Thus the cost analysis focused on providing a good definition of the costs associated with implementation over a range of scales. Overall it appears that the costs associated with the technologies is within the range of typical field survey events for other aspects of sediment assessment and characterization. Assuming that the technologies would be incorporated and applied with other traditional characterization phases of a remedial investigation or stormwater monitoring program, significant efficiencies in costs could be expected.

Implementation Status

The over-arching strategy for implementation for the technologies was based on several key components including that: the technology is well demonstrated and documented; standard operating procedures are developed and available; equipment is available on the open market; technology service providers are available to DoD users, and ; regulators have visibility of the technology. To the extent possible, we attempted to make progress on each of these components through the course of this project. The demonstrations were well documented through the ESTCP Site Selection Memorandum, Demonstration Plan, and this Technical Report, as well as through a series of conference presentations and publications. The technologies, particularly the SeDep system, would still benefit from further demonstration by early adopters under a broader range of facilities, discharge conditions, environmental settings, and regulatory applications. Standard operating procedures have been developed for all of the technologies. These are well documented in manuals provided by the equipment companies, as well as in the procedural documents contained in the ESTCP Demonstration Plan.

The equipment is all currently available from the vendors described in this document, with the exception of the SeDep system for which we were unable to finalize a relationship with a commercial vendor, although the systems are based directly on the commercially available system. Service providers collaborated in the project and have experience with the equipment. The technologies are currently in patent pending status, and there may be future opportunities for service providers to license the technology. Implementation of the technology would be well served by having the technology be picked up and promoted by a commercial consulting firm for future applications at DoD sites. The technologies have had some limited regulatory exposure. The technology was briefed and toured to staff from the San Diego Regional Water Quality Control Board during the period of the demonstrations in San Diego Bay. Results from the demonstrations in Pearl Harbor have also been briefed to the regulatory team associated with the Pearl Harbor sediment cleanup. The RPM at Pearl Harbor has been actively involved in the project and in implementing the technology at her site, and represents a key early adopter for the technology. The technology would benefit from further exposure to regulatory agencies that have oversight over stormwater and/or sediment cleanups.

1 INTRODUCTION

Source assessment and control is critical challenge for protecting Department of Defense (DoD) investments in sediment cleanup as well as in the prevention of future contaminated sediment liabilities (Strategic Environmental Research and Development Program, 2012). Stormwater sources are at the nexus of this challenge, spanning virtually every DoD coastal site, and linked to every aspect of regulatory compliance including National Pollutant Discharge Elimination System (NPDES) permitting, Total Maximum Daily Load (TMDL) actions, Environmental Restoration (ER) programs, and associated source control strategies (Figure 1). The ubiquitous and non-point source nature of these sources make them difficult to effectively characterize and control while at the same time, regulatory pressure to reduce them and cleanup adjacent water bodies is increasing. Among the key challenges of stormwater compliance and characterization are:

- What are realistic exposure scenarios that are protective of the environment but not so conservative as to be impossible to achieve?
- What is the fate and transport of the particulate fraction of these sources and their linkage to regional sediments that may be impacted by episodic discharges?
- At what point are these sources sufficiently controlled to warrant large-scale investment in remediation of the adjacent sediments?

The first aspect is fundamental to improving approaches to stormwater compliance, while the second and third are fundamental to supporting the development of rationale TMDLs, preventing recontamination of remediated sediments, and protecting DoD from future contaminated sediment liabilities.

1.1 Background

Current methods for assessing stormwater exposure, fate and transport are limited. Compliance programs generally focus on end-of-pipe monitoring for first-flush conditions. These measurements are often highly variable, and provide little insight into actual environmental exposure, impact, fate and transport (Katz et al., 2006). For large scale sources such as urban creeks and streams, three dimensional numerical models have been applied to predict exposure and transport of particles, but these models generally lack validation through direct measurement that would improve acceptance and reduce uncertainty in the results.

Methods for assessing particle transport and fate in DoD coastal harbors are also limited. Sediment transport models have been applied on larger scales, but are highly complex, and usually of inadequate resolution to resolve small stormwater discharges (Chadwick et al., 2007; Gailani et al., 2007). Field based methods that have been used include sediment sampling near outfalls, sediment traps placed near outfalls, and geochronology analysis of sediment cores collected in suspected depositions zones (Apitz and Chadwick, 2002; Magar et al., 2009; Blake et al., 2007). Sediment sampling near the outfalls provides indirect evidence of potential fate of particles, but lacks any direct linkage, and is often confounded by high spatial heterogeneity of contaminant levels in sediments. Sediment traps in active harbor areas provide a measure of sediment deposition that incorporates all forms of transport and resuspension, but are unable to

distinguish source deposits from these other depositional sources. Geochronology in active harbor areas is often confounded by historical disturbance of the sediments by dredging and resuspension events, and thus cannot be reliably applied in many of the areas of interest.

Because of the limitations of current methods, there is a high degree of uncertainty in the exposure, transport and fate associated with these sources, and new tools are needed that can help DoD to better manage these challenges. An integration of emerging technologies from the oceanographic and environmental arenas provides the basis for demonstration of a family of new assessment tools and methods that could vastly improve our ability to cost-effectively address these challenges.

Global Positioning System (GPS) drifters have been used in oceanographic applications for many years (Davis, 1985; Breivik et al., 2013; Ponte et al., 2013; Halle and Largier, 2012). The primary focus of these efforts has been “Lagrangian” tracking of water currents and properties over various scales in the open ocean, ranging from local to global. GPS drifters are an available, off-the-shelf technology that are generally comprised of a drogue or sail that attaches them to the moving water, a GPS locator that tracks their position, and a radio or satellite link that transmits the position to the user (MetOcean, 2013; Pacific Gyre, 2014; Brightwaters, 2013). The drogue is generally set to track the water at a certain fixed depth. Often they are also fitted with sensors such as temperature and salinity to record and transmit water properties as well. A recent example from our work in Pearl Harbor is shown in Figure 2, where GPS drifters were used to track currents in the vicinity of the USS Missouri and USS Arizona in conjunction with oil spill preparedness efforts.

Although they have not been extensively demonstrated in this application, these systems are ideally suited to track the exposure associated with stormwater plumes. Recent examples of GPS drifter applications to stormwater include tracking of coliforms in stormwater plumes (McCorquodale et al., 2004), and tracking of river runoff plumes on the coast of California (Ohlmann et al., 2005). The systems are low-cost, easy to deploy, and their water tracking capabilities have been well characterized. They can be configured to track near-surface water parcels, where buoyant stormwater plumes often persist, and they ideally mimic the drifting exposure scenario that is characteristic of many of the sensitive planktonic larval species that are sensitive to stormwater impacts (McCorquodale et al., 2004; Ohlmann et al., 2005; USGS, 2006). At the same time, they capture all of the complex transport and mixing processes that will provide such an improved exposure scenario compared to current end-of-pipe and grab-sample type approaches. To our knowledge, composite samplers and passive samplers have not previously been used in conjunction with GPS drifters, and this novel integration will be a key aspect of our project.

GPS drifters, gliders, and moorings have also been used extensively for profiling the upper ocean (Webb et al., 2001; Sherman et al., 2001; Bachmayer et al., 2004; University of California San Diego, 2017; MetOcean, 2013; Figure 3). For this project, we adapted a small underwater winch to control the drogue depth of a GPS drifter to allow for programming of vertical settling velocity. This means that we can program the behavior of the drifter to simulate the settling rate of particles associated with stormwater discharges. Using GPS tracking of the surface buoy, and pressure and bottom sensors on the subsurface drogue, we then detect the three dimensional trajectory and the point at which the drifter settles to the bottom, and then trigger it to return to the surface and report its position, thus quantitatively defining a depositional footprint for

particles released from that source. Surface sediment samples can then be collected from those locations to characterize recent deposition, along with sediment traps and deposition sensors.

Load-cell based scour sensors were originally developed by the United States Geological Survey (USGS) to investigate sediment bed level changes in shallow streams and rivers due to flow driven changes in scour and deposition (Carpenter, 2000; Rickly Hydrological Company, 2013; Figure 4). Previous applications include shallow placement in spawning beds for unattended monitoring of deposition and erosion, monitoring transport of bedforms, and monitoring scour at bridge piers. The current technology utilizes a load-cell sensor to weigh the sediment, water, and air above it, and an accompanying pore-pressure sensor that weighs just the water and air above it. The scour/deposition is measured as the difference between the two weights at a sensitivity and repeatability of about ± 0.01 foot of sediment thickness or less.

Scour sensors have not been previously evaluated for use in source evaluation for contaminated sediment deposition, but are ideally suited to this application for complex DoD harbors where other traditional methods are limited by resuspension, dredging and other confounding processes. We envisioned that scour sensors can be embedded in the deposition zones identified by drifter measurements and/or modeling simulations to provide a direct measurement of net deposition over both episodic and long-term time scales. To enhance the resolution of the sensor, we evaluated the use of differential pressure sensors rather than direct pressure sensors so that the signal is not swamped by deeper water sites or large scale tidal fluctuations (e.g. Paroscientific Inc., 2013). We envisioned that these sensors could be co-deployed with sediment traps during discharge events so that new deposition could be de-convolved from the total deposition into the trap. This would allow the analysis of particle material from the trap to be better interpreted as to whether it was originating from the source or from local resuspension events.

1.2 Objectives of the Demonstration

Based on the requirements described above, the objective of this project was to demonstrate a family of technologies adapted from the oceanographic and environmental arenas that could significantly improve our ability to address contaminant source exposure, transport and fate challenges at DoD coastal site in a relatively simple and cost effective way.

Through the integration of these technologies, our goal was to develop and demonstrate a spectrum of new capabilities. Our demonstration focused on three key products including:

- **Drifting Exposure System (DrEx)**: Surface GPS drifter with position data telemetry, composite sample collection and passive sampler capabilities for exposure characterization.
- **Drifting Particle Simulator (DPS)**: GPS drifter with position data telemetry, buoyancy control, bottom detection, and passive sampling capability for measurement of depositional footprints and sampling of source related particles.
- **Sediment Deposition Detector (SeDep)**: Sediment bed scour sensor with high resolution differential pressure sensor, shore cable or in situ data logging, and coupled sediment trap capabilities for simultaneous quantitative measurement of deposition rates and sampling of depositing particles.

We envisioned that these technologies would provide a broad new set of capabilities that are highly applicable to characterizing the exposure, transport and fate of stormwater contaminant sources (Figure 5). Each of these technologies underwent refinement and testing in the first year of the project prior to these field demonstrations. The current versions of the commercial prototype systems are described below.

1.3 Regulatory Drivers

These technologies are targeted to reduce DoD total ownership costs by (1) avoiding costly active stormwater Best Management Practices (BMPs) and containment systems targeted toward stormwater discharges based solely on end-of-pipe discharge violations, and (2) avoiding major costs associated with recontamination of remediated sediment sites. DoD regulatory drivers for stormwater are generally mandated under the Clean Water Act (CWA) and regulatory drivers for sediment can fall under both the CWA and the Comprehensive Environmental Response Compensation and Liability Act (CERCLA). These potential cost impacts are significant considering that installations such as Naval Base San Diego are faced with first-flush capture requirements for stormwater that could cost in excess of \$100M, and Pearl Harbor is preparing to invest ~\$40M in sediment remediation while still faced with potential source control uncertainties.

2 TECHNOLOGY

This section provides an overview of the source assessment technologies to be demonstrated including a description of the origin of the systems, the commercialized configurations, and the potential advantages and limitations of the systems.

2.1 Technology Description and Development

The technology developed and demonstrated in this project included three related systems including the DrEx, the DPS, and the SeDep. Descriptions of these systems are summarized below.

2.1.1 Drifting Exposure System

The DrEx is a surface GPS drifter with position tracking and data telemetry, onboard sensors, composite sample collection and passive sampler capabilities for exposure characterization. The system we developed in collaboration with Brightwaters Instruments is shown in Figure 6. It is based on their standard Davis/CODE (Coastal Ocean Dynamics Experiment) design but incorporates a new composite sampling capability. The combined system allows for both the tracking and sampling of surface plumes from stormwater and other discharges.

The DrEx system is based on the Brightwaters model 121 GPS/Iridium drifter. The Model 121 GPS / Iridium Drifter is a current following (Lagrangian) drifting buoy. It is released in a body of water and moves with the currents over a period of hours to months. Onboard electronics acquire a time series of positions using the GPS as the drifter moves. Positions and optional sensor data are telemetered over the worldwide Iridium satellite network and delivered to the end user using email, a web browser, or ftp. The onboard GPS receiver automatically uses corrections provided by Satellite Based Augmentation Systems (SBAS) to enhance position accuracy in areas of the world served by SBAS. Bidirectional satellite communication allows the drifter to be reconfigured after deployment. This allows the same deployment to serve multiple missions or adapt sampling based on changing conditions.

The drifter design is similar to the CODE drifter developed at the Scripps Institute of Oceanography. This design (also known as a Davis or SCULP drifter) provides excellent coupling to the surface layer and exhibits little wave rectification. The standard size hull is approximately 1 meter (40 in.) tall excluding the antenna mast and weighs about 11 kg (24 lbs). The Model 121 features a 12 channel GPS receiver and records position to 0.001 minute of latitude and longitude (1.8 meters). Absolute accuracy of the position is better than 15 meters worldwide. In areas served by one of three SBAS systems (Wide Area Augmentation System [WAAS] in North America, European Geostationary Navigation Overlay Service [EGNOS] in Europe, and MTSAT Satellite Augmentation System [MSAS] in East Asia) absolute accuracy is better than 3 meters (2 X Distance Root Mean Squared; 2DRMS). The drifter uses the Iridium satellite system's Short Burst Data (SBD) service for communication of data and commands. When scheduled, the drifter sends stored data to the end user. Positions can be sent individually as soon as they are taken for time critical tracking, or can be aggregated and sent in bursts for greater efficiency. In either case, typical latency from the time the drifter powers the Iridium transmitter until the end user receives data is less than two minutes. If a communications session fails for any reason, the drifter will automatically retain the data and transmit at a later time.

Full access to the drifter's extensive command set is available via the Iridium downlink. This allows a drifter to be reconfigured after deployment. For example, when released in an estuary where high time and space resolution is required, a drifter can be set to determine position every five minutes and transmit every position immediately. Once the drifter moves offshore, it can then be reconfigured remotely to maximize deployment endurance by taking data once an hour and transmitting a block of positions twice per day. The drifter ships provisioned for the Iridium system. Brightwaters offers an economical full turnkey service including Iridium satellite usage, data decoding, and storage. Results can be accessed via email, ftp push, or password-protected web. The drifters are designed to be reused. Brightwaters offers complete refurbishing services, and most routine maintenance can be accomplished by the end user. External parts such as sails or floats are easily replaced if damaged. The drifter hull can be opened to change batteries. Replacement battery packs are simple to make locally or can be ordered from Brightwaters.

Standard optional sensors available through Brightwaters for the Model 121 drifter include temperature with a range of -10 to +40 C and resolution of 0.01 C, and conductivity with a range of 0.01C. 0-60 mmho/cm and resolution of 0.01 mmho/cm. Other analog and digital sensors are available upon request. The integrated Brightwaters sensors allow for remote telemetry of the sensor data through the Iridium system. For this demonstration, we utilized a commercial conductivity/temperature sensor from Onset (model Hobo U24) installed on a bracket off the main hull of the drifter. The U24 is an internally logging sensor so the data were stored onboard and downloaded after each deployment.

The water sampling capability for the DrEx system was developed by Brightwaters and is commercially available as the Model 127 Programmable Automatic Water Sampler (PAWS; Figure 7). The PAWS is an oceanographic water sampling system allowing unattended collection of up to a five liter surface water sample in a sampling bag. The PAWS consists of a peristaltic pump and interface circuitry inside a watertight polyvinylchloride (PVC) case, a sampling port, and a sample collection bag housed inside a free flooding protective housing. The PAWS is intended for unattended or remote sampling on ships, fixed or drifting buoys, from docks, etc. Specifications for the PAWS component of the system are shown in Table 1. The water sampler connects to the drifter body via a lateral bracket. The pumping system is fully programmable and the controls can also be accessed in real time via the Iridium communication link.

We also evaluated the potential for integration of passive samplers into the DrEx. For metals, it was relatively straightforward to integrate the disc-type Diffusive Gradient in Thin Film (DGT) units (Figure 8) because they are capable of sufficient metal uptake over the relatively short time periods expected for the drifter deployments (1-2 days). In this case, the DGTs were easily mounted directly to the drifter frame. However, for hydrophobic organic contaminants such as Polycyclic Aromatic Hydrocarbons (PAHs) and Polychlorinated Biphenyls (PCBs), most passive samplers have exposure requirements that are on the order of weeks, even with the use of performance reference compounds to accommodate sub-equilibrium operation. To accommodate this, we tested a stand-alone pumping system in combination with Performance Reference Compound (PRC)-doped Solid Phase Micro Extraction (SPME) fibers that can provide enhanced response times on the order of 1-2 days (Figure 8). Initial results using a high K_{ow} dye surrogate (Sudan III, $\log K_{ow} \sim 6-7$) showed promising results. The system consists of a battery-operated submersible pump connected to a length of small diameter Teflon tubing where the SPME fibers were placed. Elimination rates were in the range of 1-2 days for ~80% removal of the dye surrogate from the fiber based on pre- and post-extraction spectrometry. We included this

approach during the demonstration as an initial evaluation of the potential for this approach in the field.

To implement the DrEx system, we worked closely with Brightwaters in a phased approach. A commercial prototype was developed based on our specifications and built around their original model 121 drifter system. Following completion, pier-side testing was conducted to verify the operation of the GPS tracking, the Iridium communications, and the water sampling system. Pier-side testing results for the first commercial prototype system are shown in Figure 9. Based on successful testing, nine more units were constructed and were used for the field demonstrations described here.

Table 1. Specifications for the water sampling unit on the Drifting Exposure system.

| | |
|---------------------------------------|---|
| Depth rating and pump access. | Watertight case rated for immersion to 2 meters. Access through o-ring seal for maintenance such as peristaltic tubing replacement. Pump input and output routed to bulkhead fittings in endcap. |
| Sampling pump | Peristaltic pump. Speed currently fixed at 30 rpm (approximately 0.5 ml/second with default tubing). |
| Endurance | Dependent on sampling scheme and external power. |
| Sample port | Screened port for sample collection inlet. Mounting location to be determined by end user. |
| Sample tubing | FEP. |
| Sample collection | Up to 5 liter Tedlar or PTFE gas sampling bag. Sample bag housed in free-flooding housing section so overall weight does not change during sample collection. Free-flooding section provides physical shield for sample bag, protecting it from external damage. |
| Power and command interface | Impulse Enterprise MCIL-4MP 4 pin underwater connector on 0.6 meter pigtail. Pinout: <ol style="list-style-type: none"> 1) Ground. 2) V+ power supply. 3) PAWS transmit data, RS232. 4) PAWS receive data, RS232. RS232 is at 9600 baud, 8 data bits, 1 stop bit, no parity. |
| Power requirements | 11.4 – 25.2 volts DC, 1 amp wall supply recommended. Typical power consumption at 15 VDC supply: Pumping: 510 mA. Awake: 7.5 mA Asleep: 32 uA. |
| Pump states | Idle, pulsed operation, continuous operation. |
| Pump report | Transmitted every 2 seconds when pumping or awake. Pump state, pump direction, volume count, internal humidity, minimum volume count, maximum volume count. |
| Pump commands | Stop pump, start pump continuous, start pump intermittent, set pump direction, set volume count, set maximum volume, set minimum volume, display firmware version. |
| Dimensions, construction, and weight. | 38 inches high x 5 inches diameter, case closure ring 7 inches diameter. External materials appropriate for marine and freshwater deployment: Epoxy paint, PVC and other plastics, 300 series stainless steel hardware. Easy access for servicing pump, tubing, and sampling bags. Weight in air with sample bag empty approximately 10 pounds. Approximately neutral buoyancy in water. Shipping weight 15 pounds. |

2.1.2 Drifting Particle Simulator

The DPS is based on an integration of the Pacific Gyre Microstar Lagrangian Drifter design with GPS tracking and Iridium satellite communications, and a high resolution depth-control underwater micro-winch (Figure 10). The DPS Drifter tracks water currents at depths of 1 to 20 meters, and is equipped to accommodate a range of additional sensors. The system is configured with a spherical surface float housing the GPS and Iridium satellite communications, a “Holey Sock” subsurface drogue, and is supported by data archival, mapping, web access capabilities. The system is designed to house the underwater micro-winch along the central axis of the subsurface drogue, and maintain adequate drag to drogue ratios for water depths in the range of 1 – 20 meters. A winch system with a surface float connected to the drogue was selected in favor of the original design which envisioned a buoyancy engine and no surface float. Preliminary analysis indicated that control of the vertical settling velocity with the buoyancy engine would be very challenging. In addition, using the surface float allows for constant tracking of the system and development of complete three dimensional trajectories.

The GPS system used on the DPS is a uBlox LEA 6H 50-channel receiver with SBAS capability. The GPS records data onboard as well as sending data via the Iridium system to the Pacific Gyre web server. Onboard data is stored at a rate of once every two seconds. Data are transmitted to the web server at a rate of once every five minutes. The specified accuracy of the LEA 6H is 2.5 meters circular error probable (CEP 50%) without SBAS and 2.0 meter (CEP 50%) with SBAS active. The drogue consists of a collapsible fabric cylinder supported by PVC hoops at each end. A PVC tube along the central axis of the cylinder houses the micro-winch. This tube is connected to the outer portion of the drogue by a series of axial spokes. The size of the drogue can be varied, but the drag characteristics for this application were designed around a drogue with a height and diameter of about 90 cm each. This provides adequate frontal area to overwhelm the drag associated with the surface float and the tether line so that the drifter will predominantly follow the subsurface current at the drogue depth. Performance analysis for the drogue design showed that the surface float position would not be significantly offset (<6 m) from the drogue position in water depths of 10 meters with a current shear up to 1 m/s (Figure 11). This requires a buoyancy for the surface float of about 4 kg which is achievable within the small diameter (20 cm) Microstar surface float.

In combination with the underwater micro-winch, the system provides the ability to use these drifters to mimic the settling velocities of particles by automatically adjusting the depth of subsurface drogue relative to the surface float, allowing for simulation of effective particle settling rates in ocean, river and lake currents. The underwater micro-winch is a small underwater winch that controls the distance between the surface float and the subsurface drogue of the DPS Drifter. To achieve this, the winch includes a spool, line, drive motor, controller, batteries, pressure sensor and bottom-detection sensor. The winch is programmed by the user to pay out line at a user-selectable rate in the range of typical particle settling rates. The winch incrementally pays out the line at this rate, lowering the subsurface drogue while sensing the drogue's depth in the water. When the subsurface drogue reaches a user-selectable distance from the bottom, the winch controller activates the winch to reel the subsurface drogue back to the surface (termed “reel-up”). The descent rate can be programmed to mimic effective particle settling rates in the range of the fine silt to sand sized particles that are expected to settle in the relatively near field of the discharge.

To implement the DPS system, we worked closely with the University of California San Diego (UCSD) and Pacific Gyre in a phased approach. An initial prototype was developed by a student design team at UCSD and tested in San Diego Bay. Following this development effort, a commercial prototype was developed base on our specifications and built around the Pacific Gyre Microstar drifter system. The underwater micro-winch was developed under subcontract to Zebra-Tech Ltd. Following completion, pier-side testing was conducted to verify the operation of the GPS tracking, the Iridium communications, and the vertical control system. Pier-side testing results for the first commercial prototype system are shown in Figure 12. Based on successful testing, nine more units were constructed and used for the field demonstrations described here. Technical specifications for the system are shown in Table 2.

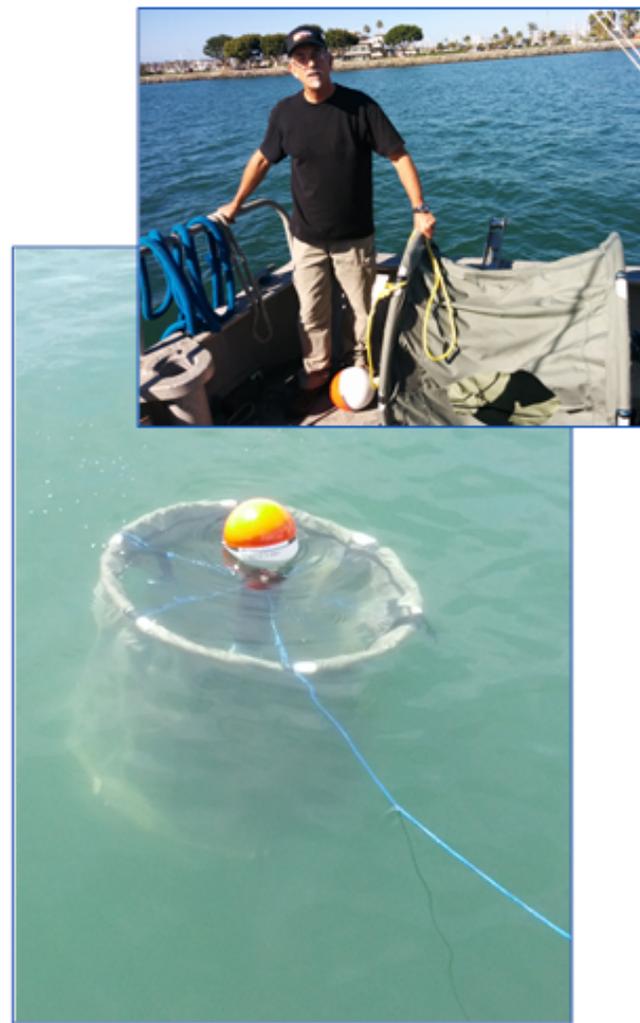

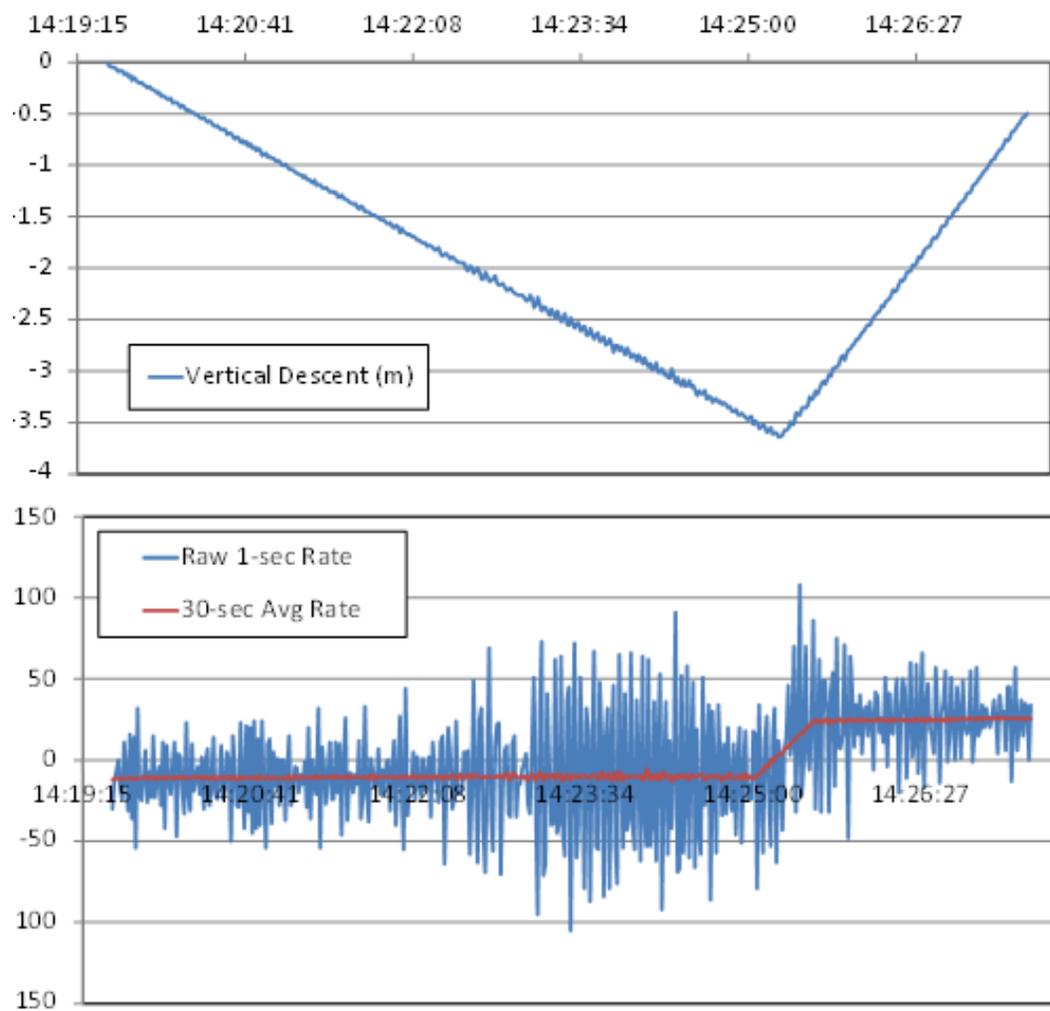

Figure 12. Prototype and testing results for the DPS system.

Table 2. Specifications for the commercial DPS system.

| | |
|------------------------------------|--|
| Surface Float Size: | Spherical 20 cm diameter with minimum 50% excess buoyancy |
| Subsurface Drogue Size: | ~90 cm wide by 90 cm deep |
| Telemetry: | Iridium SBD w/ Iridium 9602 Modem |
| Surface Float Sensors: | High-resolution sea surface temperature |
| Winch Maximum Operating Depth: | 40 meters |
| Descent/Ascent Rate: | User selectable 1 to 1500 mm/minute |
| Pressure sensor: | 0-60 meter range with 10 mm accuracy and 30 second averaging period |
| Bottom-detection sensor: | High resolution tilt sensor on adjustable aerial below the drogue |
| Winch battery endurance: | 1500 meters total winch travel (combined ascent/descent) |
| Winch Batteries: | Metal Hydride rechargeable, 9 hour recharge |
| Winch Controller/Logger: | User set start time, target descent rate, distance to bottom for triggering ascent, target ascent rate, pressure averaging period, data logging rate |
| Winch Data Collection: | Off-loadable data file consisting of time (resolution of a second), date, depth and distance to bottom |
| Subsurface Drogue Weight in Water: | Adjustable from negative 0.5-2 kg with ballast |
| Winch Size: | Cylindrical approximately 12 cm diameter by 60 cm long |

2.1.3 Sediment Deposition Detector

The SeDep system consists of a standard USGS Load-Cell Scour Sensor provided by Rickly Hydrological Corp. that was modified to incorporate a highly sensitive differential pressure sensor in place of the standard pair of absolute pressure sensors (Figure 13). The Load-Cell Scour Sensor is designed to be sensitive to small changes in sediment load and can measure both scour and deposition as well as variations such as infilling of gravel and cobbles with fine-grained sediment. Previous uses for the sensor include shallow placement in spawning beds of fish for unattended monitoring of deposition, erosion and substrate temperature, monitoring transport of bedforms in experimental flumes, and monitoring scour at bridge piers or similar structures.

The standard load-cell sensor weighs the sediment, water, and air above it, and an accompanying pore-pressure sensor weighs the water and air above it. The difference between the two weights is the weight of the sediment overlying the sensor pair. Published sensitivity and repeatability for the standard system are ± 3 mm of sediment thickness or less. With the new integration of the differential pressure sensor in place of the standard sensor pair, the depth limit of the system is increased by two orders of magnitude from 3.5 m, to 350 m, and the sensitivity is improved by about 2 orders of magnitude from 3 mm to about 0.05 mm. These improvements were critical to the application of the system for assessment of stormwater events and potential recontamination of the sediment bed. In addition, the standard unit required cables run to shore for monitoring, while the new system incorporates an onboard data logger that can be left at the site for extended periods.

In application, the sensor is buried or jetted into the sediment bed by divers, the sediment trap is staked in about 2 meters away, and the data logger is secured to the stake supporting the trap

(Figure 14). The deeper the sensor is buried, the safer it is from being scoured, the shallower the sensor, the greater the detail that can be determined from closely spaced sensors, but the greater the risk of removal by scour. Typical burial depths for depositional environments are about 5-10 cm. Deposition and/or scour events are monitored over time and a complete times-series is generated. The character of the resulting data sets can provide unprecedented insight into the nature and magnitude of events at the sediment bed including steady and episodic deposition events and scour events related to ship movements or other processes (Figure 15).

The SeDep incorporates a standard sediment trap to allow of collection and analysis of deposited sediments. The sediments traps are mounted on a stake on the sediment bed that also serves as a mounting location for the sensor data logger. Sediment traps are constructed of 6 in. diameter PVC tubing with an aspect ratio of 5:1, for a trap height of 30 inches. The traps are typically covered with a coarse mesh to prevent entrance of macrofauna, and filled with ~4 L of a solution consisting of 50 ppt brine, sodium azide (5%) to prevent biological growth, and Rhodamine dye to exhibit any disturbance of the trap during the deployment. Integration of the sediment traps provides a means of capturing the materials that are depositing on the sensor and characterizing their physical and chemical characteristics to help estimate fluxes. Shallow sediment cores can also be collected in the vicinity for similar analyses.

To implement the SeDep system, we started with a standard system from Rickly Hydrological, and carried out a phased approach of modification, testing and refinement. Two standard USGS Load-Cell Scour sensors were acquired and tested under controlled lab conditions. Differential pressure sensors were then researched and the Omega PX409 was identified as a potential replacement sensor for our targeted range of conditions. A commercial prototype was then developed that incorporates the Omega PX409 as well as the onboard data logger. The commercial prototype was then tested under controlled lab conditions (Figure 16). Initial testing revealed problems with leaks of the soldered connection and the stiffness of the stainless steel membrane used on the load cell. After a number of attempts to correct the leaks and stiffness issues, we decided to switch to a thin polycarbonate membrane adhered with an underwater marine adhesive. These systems were used during the demonstration in Pearl Harbor. After that demonstration, additional problems were identified with both the PX409 and the load cell membranes. Although the systems performed reasonably well during the deployment, the PX409 sensors were subject to corrosion and several of the units were no longer operational after the deployment. In addition, several of the membranes on the load cells became delaminated over the course of the deployment due to a failure of the adhesive. Following the Pearl Harbor deployment, the pressure sensor were replaced with a more robust sensor from Validyne (model P55E-26-2599) and the sensor was fully potted in polyurethane to protect against corrosion and leakage. In addition, the membranes were replaced with a thinner stainless steel foil using an improved soldering technique. This final design was extensively tested, but due to time constraints was not able to be deployed in a full demonstration prior to the completion of the project. Technical specifications for the final SeDep system are shown in Table 3.

2.2 Advantages and Limitations of the Technology

In general, these technologies are targeted to reduce DoD total ownership costs by (1) avoiding costly BMPs and containment systems targeted toward stormwater discharges based solely on end-of-pipe discharge violations, and (2) avoiding major costs associated with recontamination of remediated sediment sites. These potential cost impacts are significant considering that installations such as Naval Base San Diego are faced with first-flush capture requirements for stormwater that could cost in excess of \$100M, and Pearl Harbor is preparing to invest millions in sediment remediation while still faced with potential source control uncertainties. While they have some limitations, overall we expect them to add significantly to our ability to better address these critical issues. Some specific advantages and potential disadvantages of the systems are discussed below.

2.2.1 Drifting Exposure System

Current methods for assessing trajectory, exposure and fate of stormwater plumes rely on end-of-pipe sampling, fixed point measurements, and occasionally surface water mapping and modeling. The key advantages of the DrEx system over these current methods are that (1) the system inherently follows the plume without an operator having to try to find the plume, (2) the system provides an integrated measure of the exposure that occurs in the plume which is much more realistic than exposure at the end-of-pipe, (3) multiple units can be deployed to give a general estimate of the trajectory, dispersion and dilution of the plume, (4) the systems report in real time so that they can be easily found and their operation can be adjusted if necessary, and (5) the systems are relatively low cost so that loss of a unit could be accommodated in the implementation strategy.

Potential disadvantages of the DrEx system include (1) the potential for system loss through ship strike or other damage to the pressure hull, (2) potential complexities in application in active DoD harbor areas due to interference with ships, security booms, piers and operations, (3) potential challenges in operating during storm events, and (4) results are limited to the events that are monitored, say compared to a model which could potentially simulate a range of different conditions. System loss is addressed through the real-time communication and tracking capabilities of the system which should help to minimize losses. Conducting field work in active DoD harbors always requires significant effort in providing notifications and planning to minimize interference between the field work and normal operations. Monitoring storm events is always challenging from a timing perspective no matter what method is being used, and this must be minimized through preparation and pre-mobilization and having crews on-call to accommodate changing conditions. Relative to modeling, we view these direct measurements as providing the opportunity to reduce uncertainty with the many assumptions that are required in stormwater modeling, and that the two approaches can be very complimentary when used together in a systematic way.

Along with these advantages and disadvantages, there are certain underlying assumptions associated with the DrEx technology that should be understood during its application and implementation. The primary assumption is that the vertical position of the drogue is matched to the vertical position of the plume. If the plume is very shallow, or if the depth of the drogue is set too deep, the DrEx unit may not move in unison with the plume. In addition, sensor measurements and samples collected under these conditions may not be representative of the

water in the plume. Because the vertical thickness of the plume may not be known *a priori*, and may change during the course of the survey, the best approach is generally to set the drogue as shallow as possible within the limitations of the system. The user should be aware of these assumptions when applying the system.

2.2.2 Drifting Particle Simulator

Field methods for assessing the trajectory, exposure and fate of particles associated with stormwater discharges are limited. Previous approaches have included end-of-pipe measurements, fixed point measurements with optical sensors, vertical profiling with optical sensors, and installation of sediment traps. Models have also been used in this application. The key advantages of the DPS system is that it provides a direct measurement approach for mapping out deposition footprints related to these discharges. This direct linkage analysis is not currently available and is very powerful in helping to assess the fate of these particle associated contaminants and their potential to drive sediment recontamination. Specific advantages include (1) the system inherently follows the particle plume without operator intervention, (2) the system provides a complete three dimensional trajectory under complex hydrodynamic conditions that are often difficult to simulate or predict, (3) the system can accommodate different targeted settling rates and thus be tuned to the particle types of interest, (4) multiple units can be deployed to give a general estimate of the trajectory, dispersion and final deposition footprint of the particles, (5) the systems report in real time so that they can be easily found and their operation can be adjusted if necessary, and (6) the systems are relatively low cost so that loss of a unit could be accommodated in the implementation strategy.

Potential disadvantages of the DPS system are similar to those for the DrEx and include (1) the potential for system loss through ship strike or other damage or entanglement of the system, (2) potential complexities in application in active DoD harbor areas due to interference with ships, security booms, piers and operations, (3) potential challenges in operating during storm events, and (4) results are limited to the events that are monitored, say compared to a model which could potentially simulate a range of different conditions. System loss is addressed through the real-time communication and tracking capabilities of the system which should help to minimize losses. Conducting field work in active DoD harbors always requires significant effort in providing notifications and planning to minimize interference between the field work and normal operations. Monitoring storm events is always challenging from a timing perspective no matter what method is being used, and this must be minimized through preparation and pre-mobilization and having crews on-call to accommodate changing conditions. Relative to modeling, we view these direct measurements as providing the opportunity to reduce uncertainty with the many assumptions that are required in stormwater modeling, and that the two approaches can be very complimentary when used together in a systematic way.

In addition to these advantages and disadvantages, there are certain underlying assumptions associated with the DPS technology that should be understood during its application and implementation. The primary assumption is that the drogue movement both vertically and horizontally provides an adequate simulation of the movement of particles. Underlying this assumption are several considerations including the fact that the drogue is much larger than an individual particle, the drogue is programmed to sink at a constant rate, the movement of the drogue can be influenced by the surface float and winch line, and the surface float with the GPS

may not be directly aligned over the drogue. The user should be aware of these assumptions when applying the system.

2.2.3 Sediment Deposition Detector

Current methods for measuring sediment deposition associated with stormwater discharge events rely on end-of-pipe monitoring, surface sediment characterization, sediment traps and modeling. The key advantages of the SeDep system over these current methods are that (1) the systems provide a direct time-series measurement of deposition through storm events, (2) the systems are sensitive enough to distinguish small individual events, (3) the character of the time series can help to distinguish deposition from resuspension, (4) the integrated sediment trap can provide material for physical and chemical characterization with the knowledge of if that material was associated with a stormwater deposition event, and (5) the systems are relatively low cost so multiple units can be deployed to address spatial variation.

Potential disadvantages of the SeDep systems are that (1) they require divers for installation, (2) they have a limited track record and are still somewhat developmental, and (3) the sensors only measure mass and don't distinguish particle type. While diver installation can drive up costs and complexity, the systems can be left in place for significant time periods, so a relatively large amount of data can be acquired with limited deployment and retrieval diving requirements. These demonstrations should help to improve our understanding of the field performance under realistic settings. The integration of the sediment traps with the sensors provides a basis for acquiring the physical and chemical data required to supplement the time series deposition data.

3 PERFORMANCE OBJECTIVES

Performance analysis focused on the ability of the systems to provide improved exposure, transport and fate assessment for stormwater sources in a cost effective manner. A key aspect of this performance was the ability to improve our understanding of the linkage between this ongoing sources and potential recontamination of sediment. This requires the ability to accurately track the trajectory of the plume and associated particle-bound contaminants, and establish reliable measures of event-based depositional footprints. Performance was measured against performance criteria established in the demonstration plan. Performance objectives for the three technologies are summarized in Table 4 and Table 5.

3.1 Drifting Exposure System

For the DrEx system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on tracking accuracy, communications reliability, water sampler performance, and system survivability. Tracking accuracy of the GPS system is important to reliable measurements of the plume trajectory. Reliable data communications are important to the performance of the system in active harbor areas because they allow for real-time tracking without having to utilize extensive boats and crews to follow the drifters. Communications are also important for any modifications to the sampling and for final location and retrieval of the system. An important aspect of the DrEx system is its ability to collect samples during the deployment period. Reliable sample operations are reflected in the proper collection of composite sample volumes based on the programming of the system. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is a key performance metric for the systems. Survivability in this case refers to successful mission completion, without major system failures or lost units during field deployments. The primary qualitative performance object for the DrEx was that the drifters reliable track the surface plume of a stormwater discharge release. While this is difficult to determine quantitatively, a number of methods were used to give a quantitative assessment of the plume tracking performance including onboard salinity and temperature measurements, and plume tracking measurements made with water quality instruments from the survey boat during the discharge event.

3.2 Drifting Particle Simulator

For the DPS system, we established a series of quantitative and qualitative performance objectives similar to the DrEx but adapted to the particle tracking capability of the system. Quantitative objectives focus on tracking accuracy, communications reliability, settling rate performance, and system survivability. Tracking accuracy of the GPS system is important to reliable measurements of the plume trajectory. Reliable data communications are important to the performance of the system in active harbor areas because they allow for real-time tracking without having to utilize extensive boats and crews to follow the drifters. Communications will also be important for any modifications to the sampling and for final location and retrieval of the system. An important aspect of the DPS system is its ability to simulate the effective rate of settling for discharge related particles during the deployment period. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is a key performance metric for the systems. The primary qualitative performance

object for the DPS is that the drifters reliably track the particle plume of a stormwater discharge release. While this is difficult to determine quantitatively, the results were compared qualitatively to results from numerical modeling simulations for the same areas to provide a basis for assessing performance.

3.3 Sediment Deposition Detector

For the SeDep system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on deposition detection sensitivity, measurement reliability, and system survivability. Detection sensitivity is important because the goal is to be able to detect relatively small events associated with individual storm related deposition as well as longer term accumulation associated with multiple events. Measurement reliability is important because the sensors will be largely unattended and if they are not reliable then the deposition events may not be captured in the data. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is also a key performance metric for the systems. The primary qualitative performance object for the SeDep is that the system be reasonably easy to use in the field. Overly complex or difficult to deploy systems incur higher costs and are less likely to be adopted at actual sites. Details of the performance objectives, supporting measurements, and performance outcomes are provided in Section 6. A brief summary is provided below.

Table 4. Summary of project quantitative performance objectives and metrics.

| Performance Objective | Data Requirements | Success Criteria |
|---|--|--|
| Quantitative Performance Objectives | | |
| DrEx System | | |
| Tracking accuracy | GPS accuracy data and statistics during field deployments | <5 m for >90% of the deployment period |
| Communications reliability | Telemetry link data and statistics during field deployments | Reliable position data transmitted >90% of the deployment period |
| Water sampler operation | Sample volume collected over time and at completion | Reliable composite sample with total volume within 10% of target |
| System survivability under field conditions | Data and statistics on successful mission completion, system failures, lost units during field deployments | >80% survivability under field conditions |
| DPS System | | |
| Tracking accuracy | GPS accuracy data and statistics during field deployments | <5 m for >90% of the time the system is at the surface |
| Communications reliability | Telemetry link data and statistics during field deployments | Reliable position data transmitted >90% of the deployment period |
| Settling rate | Depth data from pressure sensor onboard DPS | Accurate settling rate within 10% of target rate |
| System survivability under field conditions | Data and statistics on successful mission completion, system failures, lost units during field deployments | >80% survivability under field conditions |
| SeDep System | | |
| Deposition detection sensitivity | Data from controlled tank testing and field deployments including sediment traps | Sensitivity <1 mm of deposition for typical particle sizes Comparable deposition to short term trap results |
| Measurement reliability | Differential pressure data from field deployments | Reliable pressure data collected >90% the deployment period |
| System survivability under field conditions | Data and statistics on successful mission completion, system failures, lost units during field deployments | >80% survivability under field conditions |

Table 5. Summary of project qualitative performance objectives and metrics.

| Performance Objective | Data Requirements | Success Criteria |
|---------------------------------------|--|--|
| Qualitative Performance Objectives | | |
| DrEx System | | |
| Surface plume tracking effectiveness | DrEx GPS trajectory data, onboard salinity and temperature sensor data, and MESC plume tracking data | Onboard salinity and temperature signature is consistent with plume characteristics DrEx trajectories are consistent with spatial surface plume mapping results |
| DPS System | | |
| Particle plume tracking effectiveness | DPS trajectory data from the GPS and pressure sensors, onboard turbidity sensor data, and MESC particle tracking data from ADCP and profiled sensors | Onboard turbidity signature is consistent with plume characteristics DPS trajectories are consistent with spatial particle plume mapping |
| SeDep System | | |
| Ease of installation and retrieval | Feedback from the dive team | Ability to install a typical system array within a reasonable time period of 1-2 days |

3.4 Quantitative Performance Objectives – Drifting Exposure System

3.4.1 Tracking Accuracy

The DrEx system utilizes an SBAS-corrected onboard GPS to provide accurate tracking of its location and the trajectory of the stormwater plume. GPS accuracy data and statistics were collected during field deployments at Paleta Creek in San Diego Bay. The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period provided that the SBAS differential system was active. Results based on the Trimble GeoXT GPS measurements showed 90th percentile differences of 4.9 m and 6.4 m for the Jan 5-6, 2016 event and Feb 1 event, respectively. Results from the BadElf GNSS GPS measurements showed 90th percentile differences ranging from 5.4-5.5 m for the Jan 5-6, 2016 event, and 5.0-5.6 m for the Feb 1, 2016 event. While these values and ranges generally slightly exceeded the performance objective, the objective was considered to be met because the results were generally both very consistent and also very close to the objective.

3.4.2 Communications reliability

The DrEx system uses the Iridium satellite system to communicate positions and other status and sensor data to the user via the internet. Telemetry link data and statistics for the DrEx were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. Results for communications reliability were evaluated for each of the two survey events. During the Jan 5-6, 2016 event, communications reliability ranged from a low of 59% to a high of 94%, with an overall average of 81%. During the Feb 1, 2016 event, reliability ranged from 34% to 100% with an overall average of 77%. While these levels fall somewhat short of the performance goal, experience during the events indicated that the communications reliability was generally sufficient to provide adequate information on the locations of the drifters throughout the deployments, as well as providing accurate information on the location for the retrieval.

3.4.3 Water sampler operation

A novel aspect of the DrEx system is its ability to collect composite samples while tracking the trajectory of the stormwater plume. This capability allows for simultaneous tracking and exposure quantification. To enable this, the DrEx system utilizes a low-flow peristaltic pump controlled by the DrEx unit, connected to a 5 liter sampling bag that contains the sample. Water sampler operation data were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate reliable composite sample with total volume within 10% of the user specified target. Results for water sampler operations were evaluated for each of the two survey events. For the Jan 5-6, 2016 event, percent differences between the pump estimated volume and the measured volume ranged from 14% to 100% with an overall average of 41%. Large differences were primarily attributable to leaks that developed in the sampling bags after retrieval of the drifters. Considering only the units that were operational and had no leaks, the percent difference had an average of 14%. For the Feb 1, 2016 event, percent differences ranged from a low of 1% to a high of 91% with an overall average of 20%. Prior to this event, outer sleeves were added to protect and support the sampling bags. Only one sampling bag developed a leak during this event (DrEx 109). Eliminating this unit from the analysis, the average percent difference was found to be 12%. In general, for operational units with no leaks, the performance of the sampling system provided good agreement with the post-survey volume

measurements within the range of about 12-14%. While this is slightly higher than the 10% target, it is still adequate to achieve the sampling requirements for the system.

3.4.4 System survivability

The DrEx units are designed to be deployed in harbor and coastal areas during storm events. Weather conditions during these events are often extreme, with high winds, rainfall, and waves generated by the storms. System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Paleta Creek. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). Results for system survivability were evaluated for both survey events. For the Jan 5-6, 2016 event, no drifters were lost or sustained major damage. One drifter (109) failed due to a faulty mounting bracket that caused the magnetic switch to deactivate and shutdown the system. This only required a minor repair. For the Feb 1, 2016 event, no drifters were lost or sustained major damage. One drifter (112) lost its conductivity/temperature sensor. The same drifter also had some saltwater flooding to the pump housing for the water sampler. The total damage was estimated to be less than 25% of the drifter value. Overall, the performance objective for system survivability was met because no drifters were lost or sustained major damage.

3.5 Qualitative Performance Objectives – Drifting Exposure System

3.5.1 Surface plume tracking effectiveness

The DrEx system was designed to provide a method for tracking and sampling the surface plume associated with stormwater discharges. These plumes have complex dynamics associated with the momentum and buoyancy of the plume, and the interaction with ambient tides, currents, winds and waves. The ability of the system to track the plume is important in resolving the plume trajectory under these complex conditions. DrEx GPS trajectory data, onboard salinity and temperature sensor data, and survey boat collected plume tracking data (to the extent possible) were collected during the DrEx field deployments at Paleta Creek. The goal for this qualitative performance objective was to demonstrate that the DrEx units generally tracked the stormwater plume based on the onboard salinity and temperature signature being consistent with plume characteristics. For the Jan 5-6, 2016 event, we evaluated plume tracking based on the onboard sensors and vertical profiles collected along axial transects through the plume at three different time points during the storm. Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. Vertical profile transects also indicated that the drifters generally stayed within the plume. For the Feb 1, 2016 event, we evaluated plume tracking based on the onboard sensors and surface water mapping conducted at one time point during the storm event. Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. The surface water mapping transect also indicated that the drifters generally stayed within the plume. Overall, the performance evaluation for the surface plume tracking effectiveness indicated that the success criteria were met.

3.6 Quantitative Performance Objectives – Drifting Particle Simulator System

3.6.1 Tracking Accuracy

The DPS system utilizes an SBAS-corrected onboard GPS to provide accurate tracking of its location and the trajectory of the stormwater plume. GPS accuracy data and statistics were collected during field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period. For the March 12-13, 2016 event at Oscar pier, a total of 62 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 3.4 m. For the October 28-29, 2016 event at Waiiau, a total of 28 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 4.8 m. The results indicate that the success criteria for the DPS tracking accuracy performance objective was met.

3.6.2 Communications reliability

The DPS system uses the Iridium satellite system to communicate positions and other status and sensor data to the user via the internet. Telemetry link data and statistics for the DPS were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. For both DPS survey events, the communications reliability averaged 100%. Thus the success criterion for this performance objective was met.

3.6.3 Settling Rate

The DPS system simulates particle settling using an underwater micro-winch to mimic the settling velocities of particles by automatically adjusting the depth of subsurface drogue relative to the surface float. Settling rate data were collected from the pressure sensor onboard the DPS units. The goal of this performance objective was to demonstrate accurate settling rates within 10% of target rate. The target settling rate for both survey events was 34 mm/min. For both events, the average percent difference from the target settling rate was less than 0.0%. Thus the success criterion for the settling rate performance objective was met.

3.6.4 System survivability

The DPS units are designed to be deployed in harbor and coastal areas where exposure to harsh conditions is likely. System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). For the Mar 12-13, 2016 event, no DPS units were lost, and one DPS unit sustained major damage. System survivability for this event was thus 90%. For the Oct 28-29, 2016 event, no drifters were lost or sustained major or minor damage. System survivability for this event was thus 100%. Overall, the performance objective for system survivability was met.

3.7 Qualitative Performance Objectives – Drifting Particle Simulator System

3.7.1 Particle plume tracking effectiveness

The purpose of the DPS system is to simulate the trajectories of settling particles in complex hydrodynamic environments and identify the spatial footprint of deposition that is linked to a specific discharge or release point. For this reason, the ability of the systems to track a particle plume is a key objective of the technology. Data on plume tracking was originally expected to be collected in the field when the DPS units were released during stormwater discharge events. However, the logistics of releasing the units during events proved to be difficult with limited storm events, long-distance travel to Pearl Harbor and obtaining permission for releases on short notice at the installations. As an alternative, we collected the DPS trajectory data during the field demonstrations in Pearl Harbor, and then compared those results to simulations from the available hydrodynamic model for releases at the same locations under the same conditions. The goal for this performance objective was to show that DPS units provide a qualitatively similar estimate of particle trajectories and deposition footprints as other available approaches. For the Mar 12-13, 2016 event, the two methods show good agreement, with the DPS bottom contacts generally falling within the areas where the model showed the majority of deposition associated with silt particle release from Oscar Pier. Similar results were found for the Oct 28-29 event. On the basis of these qualitatively similar results, we concluded that the success criterion for this performance objective was met.

3.8 Quantitative Performance Objectives – Sediment Deposition Detector

3.8.1 Deposition Detection Sensitivity

The SeDep uses a precision differential pressure sensor to detect sediment deposition and scour. To quantitatively test the sensitivity of the system in the lab, SeDep units were submerged in a test tank and known weights were added to the pressure plate in the form of thin sheets of rubber. The goal for this performance objective was to demonstrate that the sensitivity of the SeDep was equivalent to <1 mm of sediment deposition. Testing of the original SeDep systems using the Omega sensors showed minimum detection limits (MDLs) for thickness ranging from 0.008 to 0.014 mm with an overall average of 0.012 mm. This level of detection sensitivity was well below the success criteria. However, the sensors were found to have two issues during longer deployments in the field. First, the sensors had a tendency to drift, requiring weight tests before and after the deployment and detrending of the field results. Second, the sensors were found to corrode and several units became inoperable shortly after the first long field deployment. Based on these findings, an improved sensor (Validyne) was identified, tested, and incorporated into the system. Time constraints on the project limited the full integration and application of these new sensors. However initial lab and field testing indicated that the primary issues with the original sensors were resolved. Overall, the success criterion for this performance objective was met.

3.8.2 Measurement Reliability

The SeDep collects differential pressure data continuously at a rate of once every two seconds over periods of days to months. Data for measurement reliability were obtained from differential pressure data during the field deployments in Pearl Harbor. The goal for this performance objective was to demonstrate reliable pressure data collected >90% of the deployment period. Reliability ranged from 87% to 100% for the ten units, with an overall average of 97%.

Reliability less than 100% occurred for three units due to failure of the adhesive that was used to secure the pressure plate membrane. On the basis of these results, we concluded that the success criterion for the measurement reliability performance objective was met.

3.8.3 System survivability

The SeDep units are designed to be deployed in harbor and coastal areas where exposure to harsh conditions is likely. System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). During and following the Pearl Harbor deployment, two issues occurred that impacted the system survivability performance. During the deployment period, the pressure plate membrane on three of the units (3,7 and 10) failed, leading to a loss of pressure difference signal. This failure was considered minor damage because replacement of the membrane is a relatively small cost as a percentage of the entire system (about 10%). After recovery, the units were tested and post-survey weight calibrations were performed successfully. However, about 5 weeks after the recover, it was discovered that five of the pressure sensors (1,3,4,6, and 9) had failed, apparently due to corrosion that had taken place inside of the sensing element. Based on these failures, combined with the sensor drift issue identified for the Omega sensors, we elected to replace the Omega sensors with an improved sensor from Validyne. To further reduce potential issues with corrosion, we also fully sealed the new sensors in polyurethane. Initial pier-side testing indicates that these improvements have successfully addressed the survivability and stability issues identified during the Pearl Harbor deployment, although long-term deployments are still needed to verify the robustness of the new configuration. Overall, the survivability success metric was not met, however, the issues that were identified have been addressed.

3.9 Qualitative Performance Objectives – Sediment Deposition Detector

3.9.1 Ease of installation and retrieval

The SeDep system provides a unique capability to monitor a continuous time series of sediment deposition at a fixed location while simultaneously capturing samples for subsequent physical and chemical analysis. A key aspect of the acceptance of the technology is that it be relatively easy to install and retrieve so that a reasonable number of samplers can be used to monitor the area of interest. Data to assess the ease of installation and retrieval was collected based on field logsheets and feedback from the field and dive teams. The goal for this performance objective was to demonstrate the ease of installation and retrieval for the SeDep system, and the ability to install or retrieve a typical system array within a reasonable time period of 1-2 days. The ease of installation and retrieval was evaluated during the Pearl Harbor demonstration. The divers reported that the deployments were straightforward and the only difficulties that were encountered were deployment into an area containing coral rubble mixed with sediment that made it difficult to properly embed the SeDep unit into the bottom. Retrieval of the systems was also uneventful. The overall retrieval rate was 10 stations in less than 3 hours for a retrieval rate

of about 3.3 stations/hour. Overall, the success criteria for the ease of installation and retrieval performance objectives were met.

4 SITE DESCRIPTION

A detailed Site Selection Memorandum was prepared as part of this project and is available on request. The sites are briefly described below. The project was initially structured around two demonstrations with the first demonstration focusing on surface plume tracking with the DrEx systems for stormwater or other releases where an understanding of the plume trajectory and the exposure that occurs in the plume are key objectives. The second demonstration focused on tracking of the fate of particles associated with discharge plumes from ongoing sources and their potential impacts to sediments and sediment remedies using the DPS and SeDep systems. For the first site, we selected Naval Base San Diego (NBSD) with a focus on the surface water discharge plume from Paleta Creek. For the second site, we selected Joint Base Pearl Harbor Hickam (JBPHH) with a focus on potential ongoing sources in the area of Oscar Pier in the Entrance Channel portion of Pearl Harbor. During the course of the project, another opportunity arose to utilize the DPS system at a second site in Pearl Harbor at the former Navy Drum Storage site adjacent to the Waiiau Power Plant Area.

4.1 Demonstration 1: Naval Base San Diego – Paleta Creek

Naval Base San Diego is the principal homeport of the Pacific Fleet, consisting of 46 Navy ships, one Coast Guard cutters, seven Military Sealift Command logistical support platforms, several research and auxiliary vessels. NBSD is home to 213 individual commands, each having specific and specialized fleet support purposes. NBSD proper is comprised of over 1,600 land acres and 326 acres of water. The wet side of NBSD consists of the Bay front area west of Harbor Drive. The dry side consists of the community facilities complex east of Harbor Drive. The wet side is intensively developed and supports waterfront operations, ship berthing and maintenance, station maintenance, training, administration, and logistics functions. Operational facilities include piers, quay walls, small craft berthing facilities, fueling facilities, armories, and waterfront operations buildings. NBSD contains 13 berthing piers, a mole pier, two channels, and various quay walls that have a total shoreline measurement of approximately 5.6 miles.

Paleta Creek is a small urban creek that flows episodically from National City, CA through NBSD into San Diego Bay (Figure 17; California Regional Water Quality Control Board - San Diego Region, 2013). Paleta Creek is a highly channelized creek with the highest flow rates associated with storm events and highly variable flows for the rest of year. Extended periods with no surface flows occur during dry weather, although pools of standing water may be present. It is one of six watercourses that feed into San Diego Bay and is part of the Pueblo San Diego watershed. The watershed is ~2160 acres and is highly urbanized, with commercial and industrial land uses dominating the shoreline around the bay (Table 3; Figure 9). The land uses incorporating the largest acreage (and percent of area) in the watershed includes: low density residential, roads/freeways, military, high density residential, commercial institutional, and open space/recreation. Much bayside property is owned and operated by the U.S. Navy, and although the Navy owns only a small percentage of the watershed, they submerged lands within the creek mouth are within the Navy property line. San Diego Bay where the creek discharges is also valued as a wildlife habitat and refuge for migratory and estuarine birds, endangered species, marine mammals, and as a spawning area for near-shore marine fishes. In addition, San Diego Bay supports many recreational uses including swimming, sailing, sport fishing, and recreational boating.

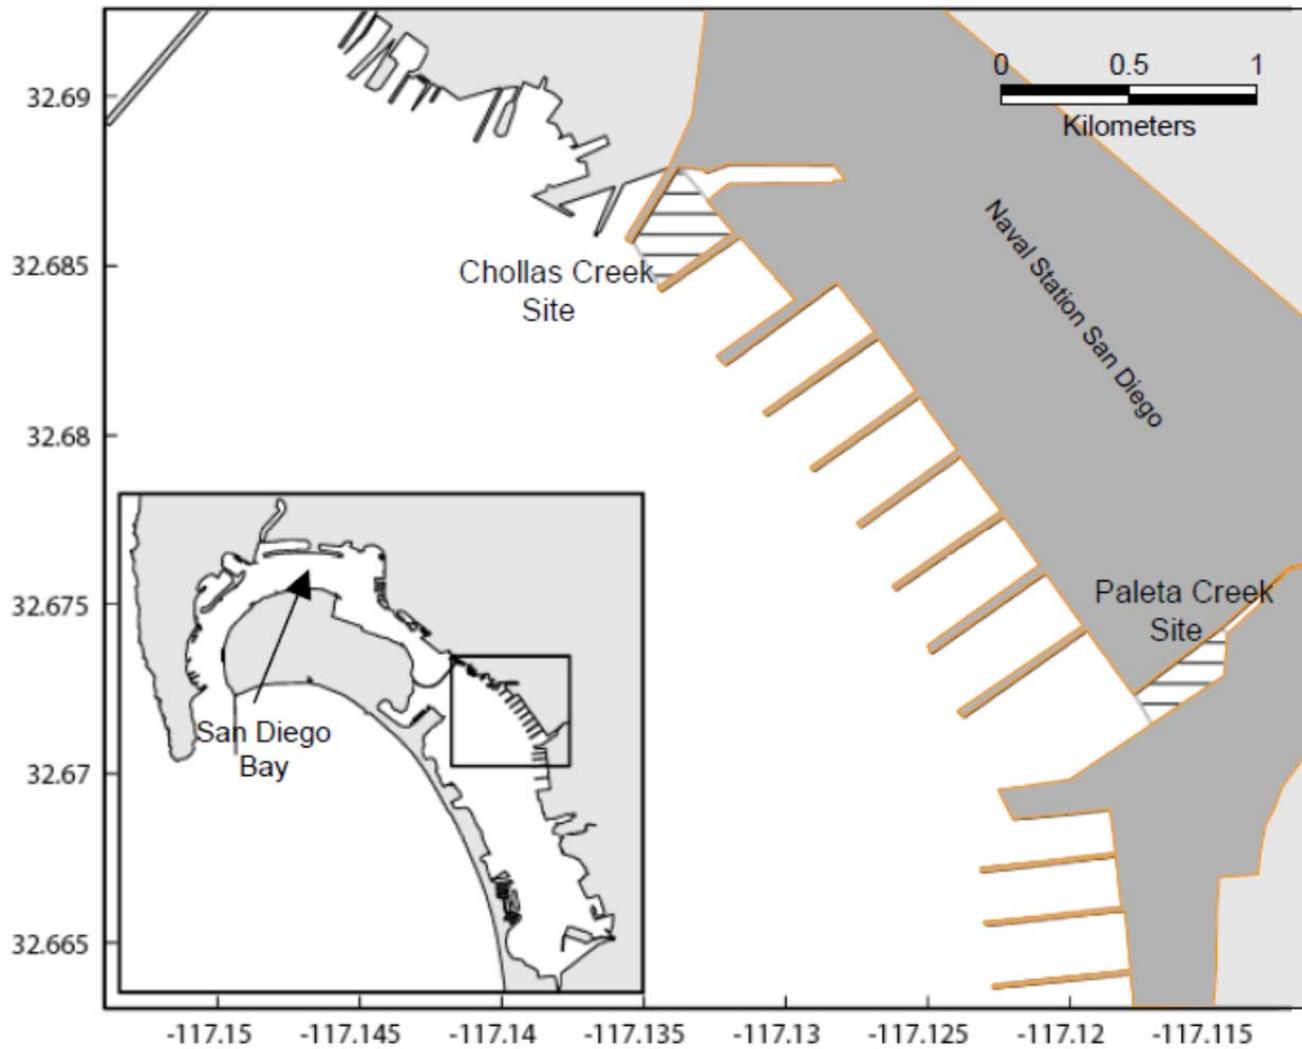

Figure 17. Location map of the Paleta Creek Site (adapted from SCCWRP and SPAWAR, 2005).

4.2 Demonstration 2: Joint Base Pearl Harbor Hickam – Oscar Pier

Pearl Harbor is a delta-shaped natural estuary located on the south-central coast of the island of Oahu, Hawaii (Figure 18). The harbor's 36 miles of linear shoreline encompass approximately 5,000 acres of surface water within four major lochs (West, Middle, East, and Southeast) and a dredged navigation channel that opens to the Pacific Ocean to the south. It is situated at the south end of the central Oahu plain, which separates the island's two mountain ranges: Waianae on the west and Koolau on the east. Pearl Harbor is a natural trap, or sink, for sediments and chemicals present in approximately 110 square miles of watershed, or 20 percent of Oahu's land surface. Pearl Harbor is a major fleet homeport for nearly 40 warships, service force vessels and submarines, and associated support, training, and repair facilities. In October 2010, Naval Station Pearl Harbor merged with adjacent Hickam Air Force Base into JBPHH. JBPHH occupies the majority of the land area immediately surrounding Pearl Harbor, and approximately 75 percent of the harbor shoreline lies within its boundaries. The base incorporates the following major activities: Naval Station Pearl Harbor, Naval Submarine Base, Hickam Air Force Base, Naval Supply Systems Command Fleet Logistics Center, Pearl Harbor Naval Shipyard and Intermediate Maintenance Facility, Naval Facilities Engineering Command Hawaii, JBPHH West Loch Annex, and the Naval Sea Systems Command Detachment/Naval Inactive Ship Maintenance Facility.

Oscar Pier is located in the Entrance Channel of Pearl Harbor (Figure 19). The pier extends from the southeast to the northwest along the western portion of shipyard area adjacent to Drydock 4. The pier area is actively supporting shipyard operations at JBPHH. NPDES discharges are present near the entrances to Drydocks 4, and stormwater discharge points line the perimeter of Oscar pier, draining the adjacent areas of the shipyard and the base. Most of the drainage areas are industrial and dominated by buildings and paved impervious surfaces although there are some recreational, residential and open spaces in the area as well.

4.3 Demonstration 3: Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area

The study area for the additional DPS survey was focused in the vicinity of the Waiiau Power Plant. This area is designated for sediment remediation as decision unit DU E-2 (Figure 20) where the contaminant of concern is Total PCBs. DU E-2 is located along the northwest shoreline of East Loch, off the Waiiau Power Plant, and is composed of two sub-areas: a deeper water sub-area east of the sheet piling groin structure extending out from the power plant, and a smaller sub-area located near the west end of the power plant property. The main power plant discharge outfall is located east of the groin structure, in the primary sub-area of the DU. A residential area lies adjacent to the eastern portion of the DU and the former Navy Waiiau Drum Storage Facility site was located to the east of the residential area in what is now Neal S Blaisdell Park (Figure 21). Potential contaminant sources in DU E-2 include point and non-point sources from surrounding commercial/industrial properties. Contaminant distribution data suggest that surface water runoff and/or the storm drain outfall associated with the Waiiau Power Plant are the primary contaminant sources for DU E-2. Available evidence and contaminant distributions indicate that previous or current Navy activities have not contributed to the PCB contamination reported for this DU. However, recently, concerns have been raised with respect to potential historical releases from the former Waiiau Drum Storage Facility site located to the east of DU E-2. Historical drawings and aerial photographs indicate the potential operation of an oil-water separator (OWS) at the southwest corner of the site. There is speculation that this OWS may have had a discharge path via a pipe leading southward into Pearl Harbor. Determining whether or not there is a likely hydrodynamic connectivity between the presumed outfall location and the contamination at DU E-2 will help to understand the potential influence of this suspected historical source area.

5 TEST DESIGN

The project followed an approach that consisted of five primary tasks (Figure 22). Task 1 focused on system integration and testing for the three technologies. Task 2 was focused on planning including site selection and development of the demonstration plan. Subsequent Tasks 3-4 entailed the execution of the field demonstrations, and Task 5 encompassed the performance and cost analysis based on the demonstrations. Specific aspects of the experimental design for the field demonstrations are detailed below.

5.1 Conceptual Experimental Design

The project incorporated three demonstrations. The focus of the first demonstration was on surface plume tracking and took place at NBSD. The second and third demonstrations focused on particle deposition tracking and took place at JBPHH. Conceptual designs for each of the demonstrations are described below.

5.1.1 Field Demonstration 1: Naval Base San Diego – Paleta Creek

The first field demonstration focused on the DrEx system at a NBSD where stormwater exposure is a concern from a compliance perspective as well as a recontamination perspective. In this demonstration, we deployed a set (10) of DrEx units at the discharge point of Paleta Creek, a small urban/industrial creek that drains through NBSD. The deployments were timed to occur with the first flush (30 minutes) of two significant storm events (predicted rainfall >0.2 inches). The systems were tracked while the sensor data, composite samples, and passive samples were collected to quantify trajectories and exposures over a period representative of the plume dispersion time (6-12 hours). Tracking was conducted from a small boat using the satellite tracking system and online data access that are part of the DrEx system. Provisions were made for units that become fouled with the shoreline or other obstacles. At the end of the deployment, the units were retrieved, the data downloaded, and the composite and passive samples processed. Composite samples were analyzed for key physicochemical parameters including temperature, salinity, total suspended solids (TSS), pH, metals (copper, zinc, lead) and organics (PAHs, Pesticides and PCBs). Samples were also evaluated using standard laboratory toxicity tests. A conceptual model for the demonstration is shown in Figure 23.

5.1.2 Field Demonstration 2: Joint Base Pearl Harbor Hickam – Oscar Pier

For the second demonstration, we targeted application of the DPS and SeDep systems for tracking particle deposition associated with potential sediment recontamination. This demonstration was planned for stormwater outfalls in the vicinity of Oscar Pier within the Entrance Channel at JBPHH adjacent to targeted sediment cleanup units. In this demonstration, we deployed DPS units at the discharge point of the target source to simulate particle trajectories. These deployments were made in the absence of a storm event to evaluate the general depositional footprint associated with tidal transport away from the outfall area. The underlying assumption was that the momentum of the discharge is quickly dissipated, and the transport was tidally dominated. Tracking was conducted from a small boat using the satellite tracking system and online data access that are part of the DPS system. Provisions were made for units that become fouled with the shoreline or other obstacles. Based on results from this initial phase, we

placed SeDep units in a distributed pattern throughout the estimated depositional footprint. These were left in place through the course of 2-3 stormwater discharge events. At the end of the deployment, the units were retrieved, the data downloaded, and the SeDep samples processed for analysis of physical and chemical characteristics. A conceptual model for the demonstration is shown in Figure 24.

5.1.3 Field Demonstration 2: Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area

For the third demonstration, an additional opportunity arose for a targeted application of the DPS system for tracking particle deposition associated with a potential historical contaminated source. This demonstration was planned for the presumed historical Navy OWS outfall offshore from the former Navy Waiiau Drum Storage Facility site in what is now Neal S Blaisdell Park. In this demonstration, we followed a similar approach to the conceptual approach at Oscar Pier but with no SeDep deployments. DPS units were released at the discharge point of the target source to simulate particle trajectories. During these events, the DPS systems were tracked to quantify the three dimensional trajectories and deposition footprints over a period of 12-24 hours or as required for the units to reach the bottom. Tracking was conducted from a small boat using the satellite tracking system and online data access that are part of the DPS system. Provisions were made for units that become fouled with the shoreline or other obstacles. At the end of the deployment, the units were retrieved and the data downloaded. A conceptual model for the demonstration is shown in Figure 25.

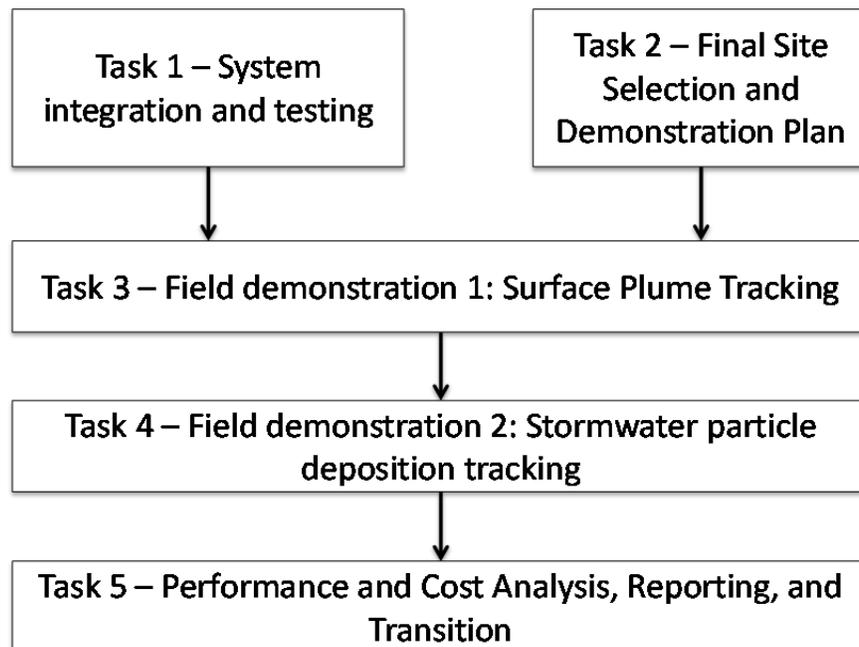

Figure 22. Flow diagram for the project approach.

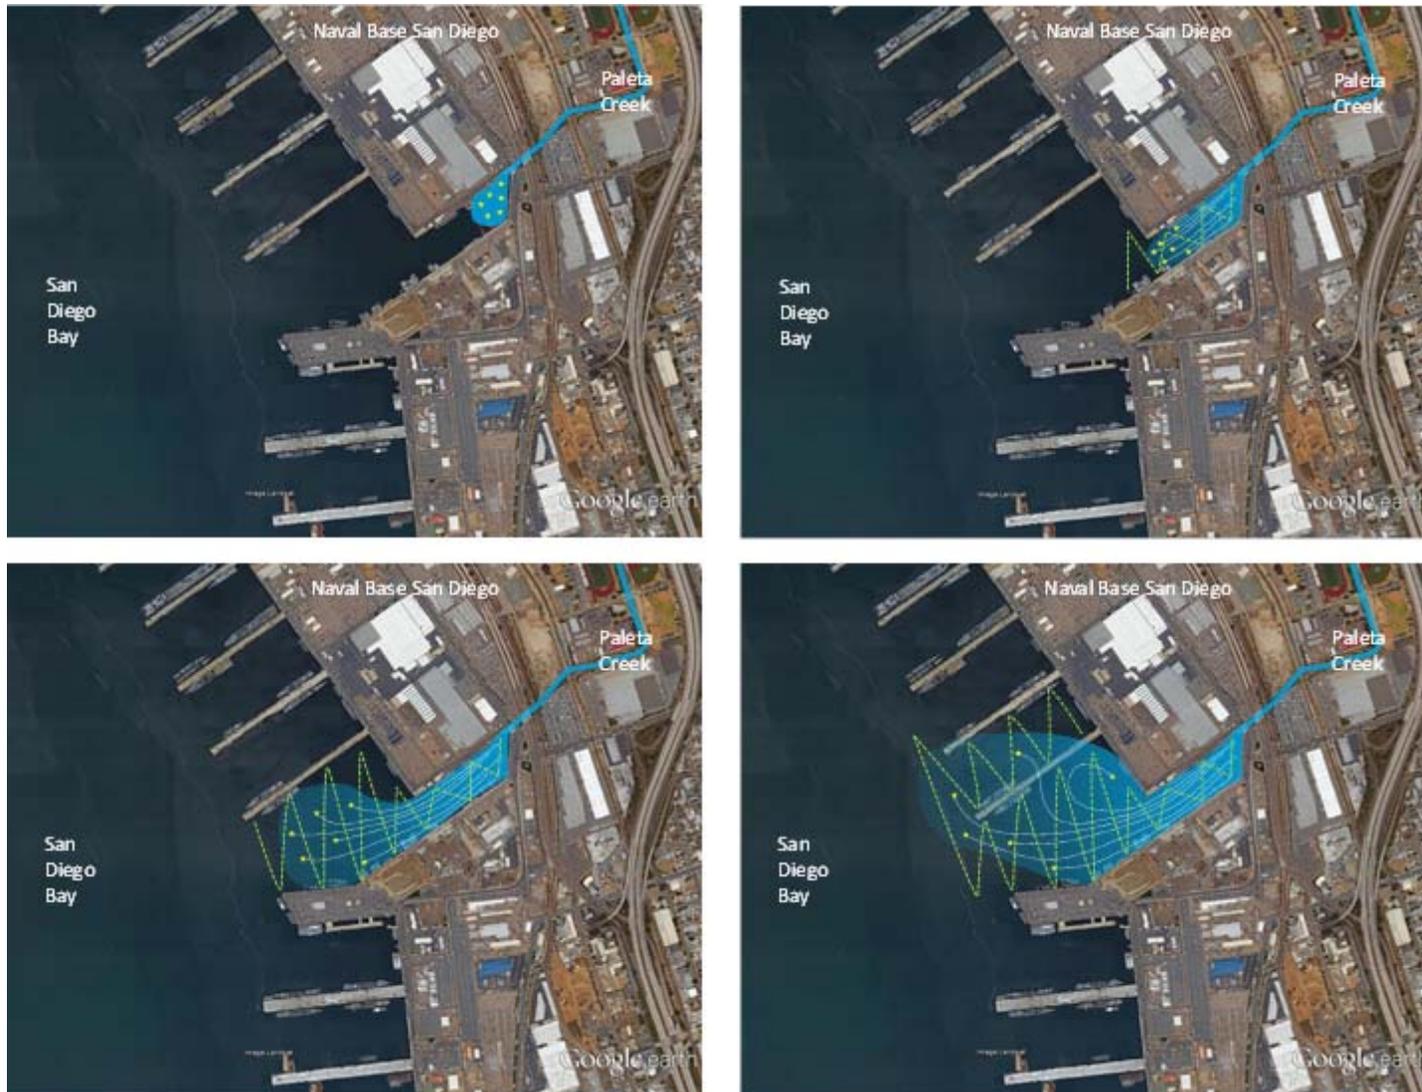

Figure 23. Conceptual diagram of the DrEx demonstration approach with surface drifters released in the first-flush event at Paleta Creek and tracked of the course of the storm (yellow stars and white trails). Surface water mapping will be performed in the plume area to verify the tracking of the plume by the drifters (green track lines).

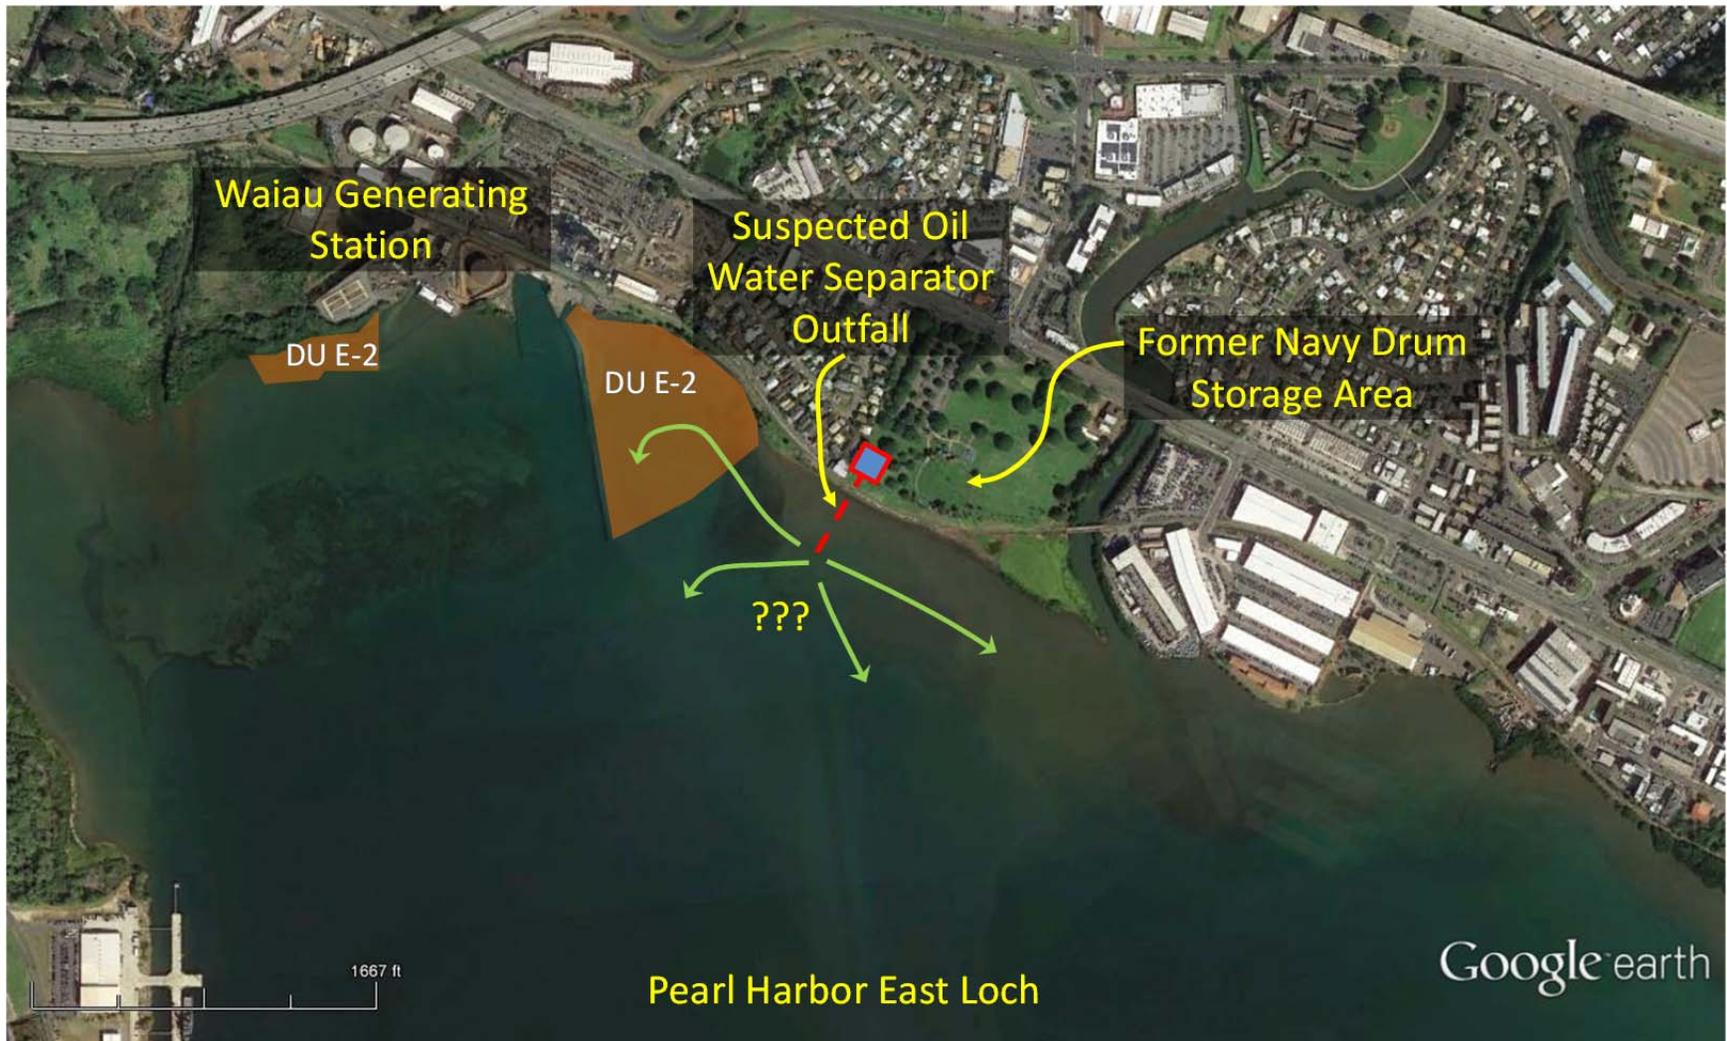

Figure 25. Conceptual diagram for the DPS demonstration approach for the suspected OWS outfall in Pearl Harbor in the vicinity of the Waiau Power Plant.

5.2 Baseline Characterization Activities

Baseline characterization activities for the sites are described below. The selected demonstration sites have been the subject of significant site characterization efforts that formed the basis for the baseline characterization.

5.2.1 Naval Base San Diego – Paleta Creek

A number of studies have been conducted to characterize the nature and extent of contamination, the persistence of contamination, the cause of the toxicity, the loading from the watershed, and the linkage of the creek discharges to the sediments in the Paleta Creek mouth area (Figure 17). To help define the baseline conditions and understanding of the site, these studies were reviewed and are briefly summarized below.

5.2.1.1 Regulatory Drivers

The State Water Board identified the 7th Street Channel/Paleta Creek as a high priority candidate toxic hot spot due to repeat amphipod sediment toxicity findings and the presence of multiple degraded benthic communities in the Consolidated Toxic Hotspots Cleanup Plan (State Water Resources Control Board, 1999). Paleta Creek was originally listed on the 303(d) list as impaired primarily because of non-attainment of the toxicity water quality objective (WQO) promulgated for the protection of designated beneficial uses in San Diego Bay. Monitoring data collected during the investigation for the Bay Protection and Toxic Cleanup Program (BPTCP) indicated that sediment toxicity, sediment chemistry, and benthic community measurements exceeded the toxicity WQO. The shoreline segment located at the mouth of Paleta Creek was listed for toxicity water quality impairments resulting in benthic community degradation.

In 1995 and 1997, Chadwick et al. (1999) performed a detailed physical, chemical, and biological characterization of the sediment at 5 stations within Naval Base San Diego and a reference station, including a station at the mouth of Paleta Creek. The Paleta Creek station was found to contain one of the highest organic chemical concentrations within Naval Base San Diego. Sediment assessment studies, conducted in 2001 and 2003, characterized the extent of sediment contamination, toxicity, benthic community impacts, and bioaccumulation. These studies confirmed water quality impairments at the mouth of Paleta Creek (SCCWRP and SPAWAR, 2005; Brown and Bay, 2005). The Southern California Coastal Water Research Program (SCCWRP) and Space and Naval Warfare Command (SPAWAR) (2005) reported that the area of “likely” impairment for aquatic life, based on sediment chemistry, toxicity and benthic community effects (or the triad), was a subset of four inner creek stations. The increasing gradient of impairment toward the inner creek mouth stations was spatially consistent with a source of pollution entering from Paleta Creek itself, or from the shoreline activities located adjacent to the site where tidal exchange can transport pollutants into creek mouth and channel areas.

The high content of fine grained sediments at the inner creek stations indicate that this is a depositional environment containing enriched total organic carbon (TOC) levels indicating a higher than normal loading of organic matter observed for San Diego Bay. A likely source of the organic matter is the urban runoff conveyed from the upland areas of Paleta Creek. The Phase I Sediment Assessment (SCCWRP and SPAWAR, 2005) reported that the classification of some outer Paleta Creek stations as “possibly” impaired was driven by the co-occurrence of elevated

chemistry and benthic community impacts; while sediment toxicity at the outer stations was observed not to be elevated relative to the baseline conditions. The results of toxicity identification evaluation (TIE) studies identified that the probable cause of sediment toxicity was the presence of elevated concentrations of organic chemicals (Greenstein et al., 2005). The sediment toxicity and benthic community effects at the creek mouth area are believed to be the result of elevated concentrations of Chlordane, PAHs, and PCBs, although some metals may also contribute to impairment.

5.2.1.2 Potential Ongoing Sources

Storm water data collected in Paleta Creek above the tidal influence were used to identify potential pollutant sources; whereas sediment data collected near the mouth of Paleta, Chollas, and Switzer Creeks were used to confirm impairment and relate pollutant loading with pollutant deposition and impairment. Dry weather flows to the bay were not measured as these were assumed to be negligible sources for pollutant loading to the impaired waterbodies. Multiple point and nonpoint sources discharge pollutant loads into the mouth of Paleta Creek. Point sources typically discharge at a specific location from pipes, outfalls, and conveyance channels. Nonpoint sources, such as sheet flow or atmospheric deposition, are diffuse in nature and have multiple routes of entry into surface waters. The pollutants can be deposited either directly to a waterbody or onto land surfaces where the pollutants wash off during storm events. Storm water runoff from urbanized areas flows off of land with a number of different uses, including residential uses, commercial and industrial uses, roads, highways and bridges (Figure 26; Table 6). Essentially, any surface which does not have the capability to pond and infiltrate water will produce runoff during storm events (USEPA, 1999). Sources of pollutants can include storm drain discharges, discharges or spills from permitted industrial facilities, illicit discharges, sewage spills, or other nonpoint sources.

The San Diego Water Board regulates storm water discharges by issuing Waste Discharge Requirements (WDRs) that implement federal NPDES requirements. Essentially all sources (point and nonpoint) in the watershed enter Paleta Creek through the storm water conveyance systems that are regulated through the NPDES permits. Other likely point and nonpoint source pollutant loads in the creek include storm water runoff from adjacent industrial discharges (regulated by individual WDRs), sediment resuspension and flux, and direct atmospheric deposition of pollutants to the surface of the waterbody.

While the waste loads of PAHs are believed to be associated with ongoing activities, such as automobile and truck emissions in the watersheds, the waste loads of chlordane and PCBs are believed to reflect residues accumulated from historical uses, applications, or spills that contaminated soils within the watersheds and act as ongoing sources. In spite of these compounds being banned in the U.S., residual concentrations of these legacy pollutants continue to remain elevated within the watershed and within bay sediments.

Chlordane was primarily used as a pesticide to control subterranean termites on buildings, insects on agricultural crops, and residential lawns and gardens. In 1988, all chlordane uses, except for fire ant control, were voluntarily suspended in the United States (National Pesticide Telecommunications Network, 2008). Chlordane can still be legally manufactured in the U.S. for sale or use by foreign countries. Although it is no longer used in the U.S., chlordane persists in the environment, adhering strongly to soil particles. The most likely route for chlordane to enter the water is from urban and agricultural soils, as its tendency is to adsorb to particulates before

entering a body of water. Therefore, the most likely source of chlordane in the watershed is storm water runoff carrying chlordane attached to eroded sediment particles.

PAHs are a group of over 200 different chemicals. They naturally occur in coal and crude oil and as byproducts in emissions from combustion of fossil fuels, forest fires and volcanoes. Most PAHs entering the environment are formed as byproducts of burning organic material (coal, oil, wood, gasoline, garbage, tobacco, and other organic material) or in certain industrial processes. They are also present in used motor oil, used hydraulic oil, tire particles, asphalt roads, coal, and coal tar. Wild fires and volcanoes are also natural sources of airborne PAHs (Agency for Toxic Substances and Disease Registry, 1995; National Research Council, 1983). About two-thirds of PAHs in aquatic systems are associated with particles (Agency for Toxic Substances and Disease Registry, 1995). Important sources of PAHs in surface waters include deposition of airborne PAHs, municipal waste water discharge, urban storm water runoff particularly from roads, runoff from coal storage areas, effluents from wood treatment plants and other industries, oil spills, and petroleum pressing operations (Agency for Toxic Substances and Disease Registry, 1995). A Southern California study that included San Diego Bay investigated cross-media transport of PAHs and found that the sediment in San Diego Bay was a source of PAHs to the water column, and the water column was a source to the atmosphere (Sabin et al., 2010). It is assumed that the primary source of PAHs to the San Diego Bay shorelines is urban storm water runoff where most airborne PAHs are deposited on the land (e.g., through precipitation or indirect atmospheric deposition) and are transported to the bay through storm water runoff.

PCBs are mixtures of up to 209 individual chlorinated compounds (known as congeners). They were used in a wide variety of applications, including dielectric fluids in transformers and capacitors, heat transfer fluids, and lubricants (Agency for Toxic Substances and Disease Registry, 2000). PCBs were formerly used in the U.S. as hydraulic fluids, plasticizers, adhesives, fire retardants, way extenders, de-dusting agents, pesticide extenders, inks, lubricants, cutting oils, in heat transfer systems, and in carbonless reproducing paper (USEPA, 2009). The manufacture of PCBs was prohibited in 1976 because of evidence that they were accumulating in the environment and causing harmful health effects. Although it is now illegal to manufacture, distribute, or use PCBs, these synthetic oils were used for many years as insulating fluids in electrical transformers and in other products such as cutting oils. Products made before 1977, which may contain PCBs include old fluorescent lighting fixtures and electrical devices containing PCB capacitors, hydraulic oils, and old microscope oils. Historically, PCBs have been introduced into the environment through discharges from point sources, and through spills and accidental releases.

5.2.1.3 Transport and Distribution to San Diego Bay

During storm seasons, freshwater inflows and contaminated sediment from runoff over the watershed are discharged into the San Diego Bay from Paleta Creek. The transport and depositions of these contaminated sediments in the creek mouth regions were previously studied by using the 3D hydrodynamic and transport model, Curvilinear Hydrodynamics in Three Dimensions (CH3D; Chadwick et al., 2005). Creek loadings of freshwater and TSS from the three creeks were calculated using the watershed model, Loading Simulation Program in C++ (LSPC). Using the CH3D model, 6 historical storms were simulated covering the ranges of the storm strength during 2001-2006. For each storm, the study determined the freshwater plume dynamics, and how much TSS load was deposited within the creek mouth region (Figure 27). Retention factors and attenuation factors of contaminants from the creek loads were estimated.

These factors quantify the change of the contaminant mass and sediment mass between the creek loads and the trapped deposits, due to contaminant partitioning and the trapping efficiencies associated with different particle sizes.

Table 6. Land use characteristics and areas of the Paleta Creek watershed (based on data from California Regional Water Quality Control Board - San Diego Region, 2013).

| Land Use | Area (acres) | % Total |
|--------------------------|--------------|---------|
| Agriculture | NA | NA |
| Commercial | 81.58 | 3.8% |
| Freeway | 127.34 | 5.9% |
| High Density Residential | 182.58 | 8.5% |
| Industrial | 10.7 | 0.5% |
| Institutional | 85.39 | 4.0% |
| Low Density Residential | 866.22 | 40.1% |
| Military | 192.17 | 8.9% |
| Open Space | 52.27 | 2.4% |
| Recreation | 65.86 | 3.0% |
| Road | 469.91 | 21.7% |
| Rural Residential | NA | NA |
| Transportation | 19.39 | 0.9% |
| Water | 7.26 | 0.3% |
| Total | 2160.7 | |

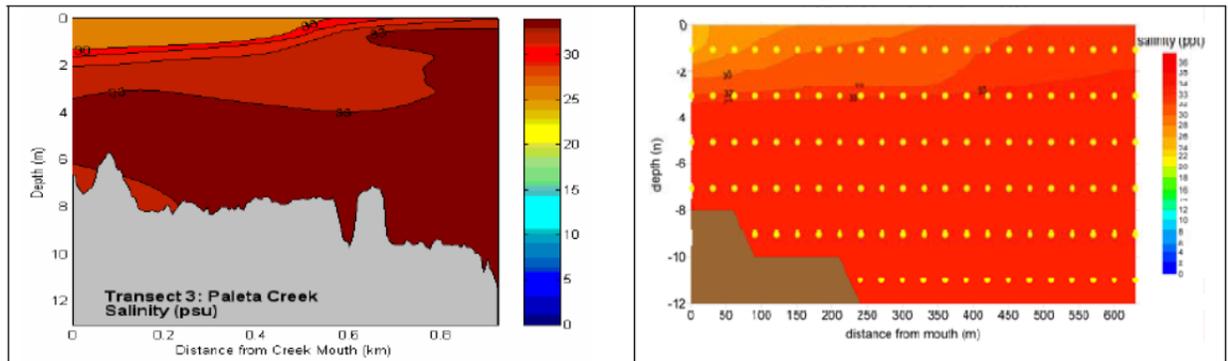

Figure 27. Measured (left) and modeled (right) vertical section of the Paleta Creek discharge plume during a typical storm event (Chadwick et al., 2005).

5.2.2 Joint Base Pearl Harbor Hickam – Oscar Pier Area

Extensive baseline assessment for the Oscar Pier area in JBPHH (Figure 18) has been carried out under the Remedial Investigation and Feasibility Studies carried out by the Navy over the last several years. A summary of the findings from those studies is presented below.

5.2.2.1 Regulatory Drivers

The Oscar Pier area (Figure 19) is subject to a range of regulatory drivers from the CERCLA, NPDES and stormwater related requirements. The area is also within the navigation footprint and is thus also subject periodically to regulations associated with the dredging program. This demonstration effort will focus on drivers associated with CERCLA cleanup of harbor sediments, but is also related to potential ongoing sources from NPDES and stormwater sources (US Navy, 2015). The sediments of Pearl Harbor adjacent to Oscar pier are being investigated for cleanup as part of a harbor-wide assessment. Oscar Pier resides within a cleanup decision unit in the Entrance Channel called N-2 (Figure 28). The sediments in this decision unit generally have the highest levels of contamination relative to other areas of the harbor.

DU N-2 is adjacent to the western shoreline of the Entrance Channel of Pearl Harbor and comprises an area of approximately 26.7 acres, including offshore areas near Dry Dock 4. The shoreline along the DU is composed predominantly of piers and wharves that support Navy activities. The entire DU is located within the harbor's maintenance dredging footprint; therefore, the water depths within the DU are linked primarily to the maintenance dredging footprint depth requirements. The majority of water depths within the DU are 40–50 feet MLLW with shallow water in the range of 10-20 feet toward the southern range of the area along the shoreline. The sediment of DU N-2 is characterized by silts and clays of lower liquid limit and plasticity, with an average TOC of 1.04 percent. Contaminants of concern (COCs) identified for sediments within DU N-2 are cadmium, copper, lead, mercury, zinc, and total PCBs.

5.2.2.2 Potential Ongoing Sources

Potential ongoing non-point sources include contributions from urban and industrial lands surrounding the harbor that discharge into the DU through direct surface water. Potential point sources for DU N-2 include docks and piers, releases from ships, storm drain outfalls that may convey runoff from surrounding Navy IR sites, and permitted industrial discharges from Dry Dock. In addition, several Navy buildings have been identified as potential or reported sources of sediment contamination that could impact DU SE-1 via the storm drain system. High total PCB concentrations (670-1000 µg/kg) were reported for surface sediments in the Pearl Harbor Sediment Remedial Investigation/Feasibility Study (RI/FS) off storm drain outfalls near Dry Dock 4; these concentrations may potentially be attributable to the outfalls. The NPDES permit for six outfalls from the four dry docks in Pearl Harbor Naval Shipyard allows for discharge of wastewater from caisson leakage, rainfall, groundwater seepage, single-pass cooling, pump test tailwater, hydroblast tailwater, and hull rinsing. The highest potential for recontamination in DU N-2 is thought to be associated with exposure of contaminated subsurface sediments during maintenance dredging and discharge of contaminated sediments from the storm drain outfalls. Sampling results indicate high COC concentrations in sediment near the storm drain outfalls (Figure 29). Additional geochemical association analysis performed to evaluate the relationship between metal COCs and iron as a reference metal indicates that most storm drain outfalls are enriched in metal COCs relative to the iron content compared to clean stream sediments and sediments collected from areas with no exceedances.

5.2.2.3 Transport and Distribution to Pearl Harbor

Sediment transport modeling, radioisotope data, and shear stress data indicate that DU N-2 is a depositional environment and that erosion in the DU due to natural processes is not likely to expose buried sediments. The net sediment deposition rates as measured from the 2009/2012 radioisotope data are 0.44 cm/y for under piers and 1.1 cm/y for overwater areas. The only potential erosion mechanisms identified for DU N-2 are propeller wash and extreme events (e.g., hurricanes). The vertical profile data indicate concentration trends toward the surface increasing in the areas off Dry Dock 4 and the Oscar piers, indicating potential ongoing sources in these areas or possible exposure of deeper sediment contaminants due to navigation dredging. In general, particulate-based contamination from ongoing sources in the area is expected to deposit to the sediment bed within the tidal distribution distance of the release point.

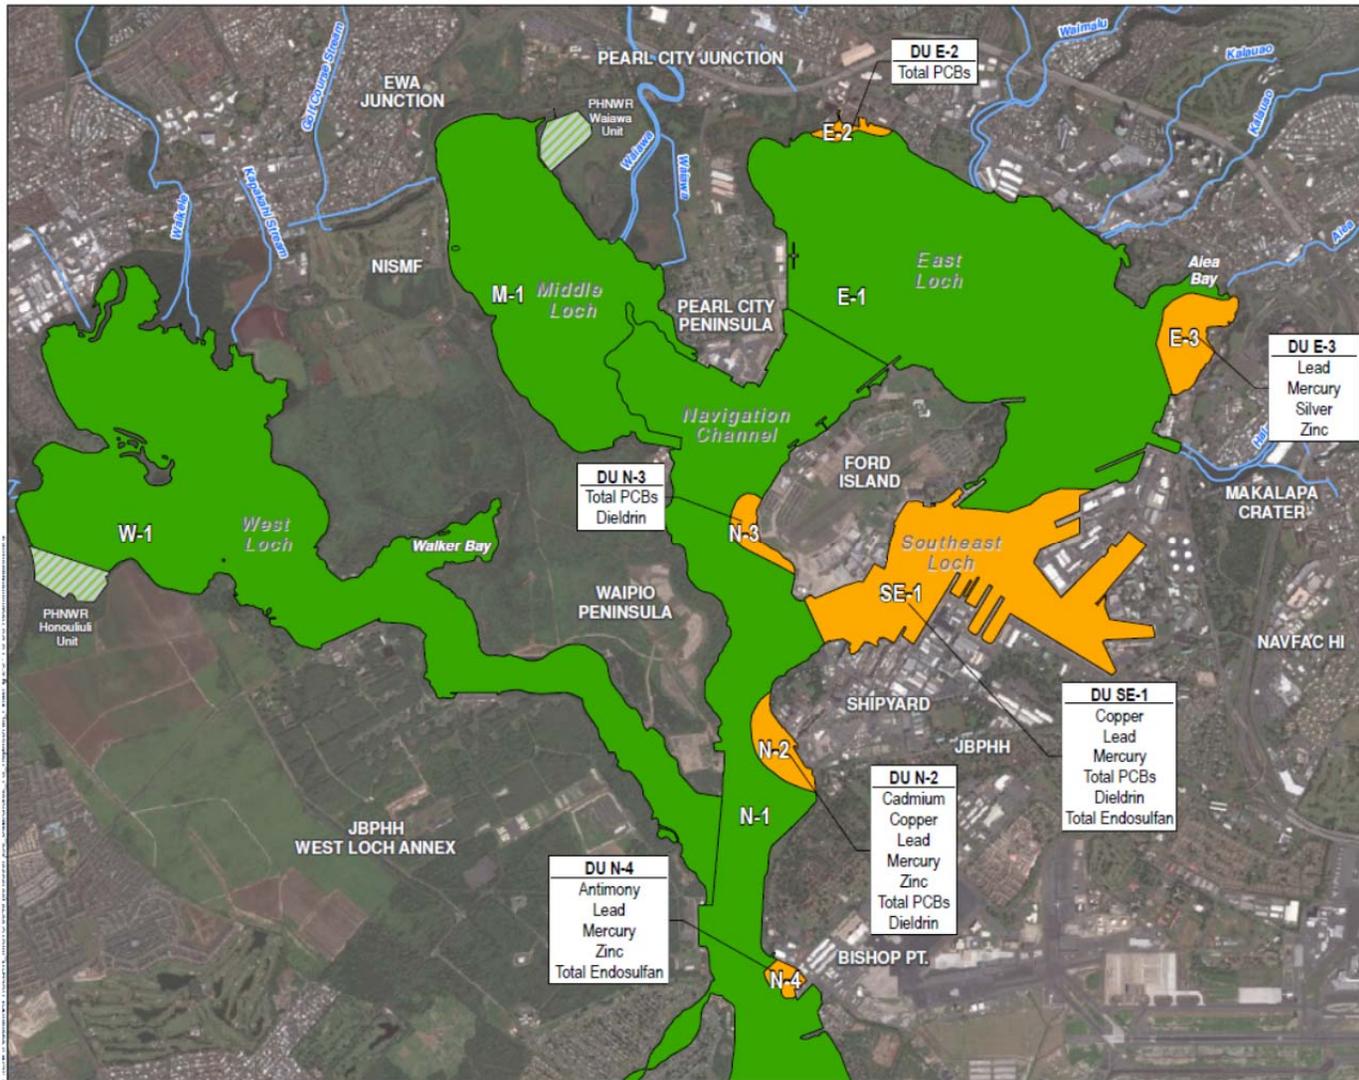

Figure 28. Decision units for the sediment cleanup in Pearl Harbor (adapted from US Navy, 2015).

Figure 29. Surface sediment contamination levels in the vicinity of outfalls in the Oscar pier area (adapted from US Navy, 2015).

5.2.3 Joint Base Pearl Harbor Hickam – Waiau Power Plant Area

Extensive baseline assessment for the Waiau Power Plant area in JBPHH has been carried out under the Remedial Investigation and Feasibility Studies carried out by the Navy over the last several years. A summary of the findings from those studies is presented below.

5.2.3.1 Regulatory Drivers

The Waiau Power Plant area is subject to a range of regulatory drivers from the CERCLA, NPDES and stormwater related requirements. The area also borders on the navigation footprint and is thus also subject periodically to regulations associated with the dredging program. This demonstration effort will focus on drivers associated with CERCLA cleanup of harbor sediments, but is also related to potential ongoing sources from NPDES and stormwater sources (US Navy, 2015). The sediments of Pearl Harbor adjacent to Waiau Power Plant are being investigated for cleanup as part of a harbor-wide assessment. Waiau Power Plant resides within a cleanup decision unit in East Loch called E-2 (Figure 20). The sediments in this decision unit generally have high levels of contamination relative to other areas of the harbor. DU E-2 is located along the northwest shoreline of East Loch, off the Waiau Power Plant, and is composed of two sub-areas: a deeper water sub-area east of the sheet piling groin structure extending out from the power plant, and a smaller sub-area located near the west end of the power plant property. The main power plant discharge outfall is located east of the groin structure, in the primary sub-area of the DU. A residential area lies adjacent to the eastern portion of the DU and the former Navy Waiau Drum Storage Facility site was located to the east of the residential area in what is now Neal S Blaisdell Park (Figure 21). Water depths within the DU are relatively shallow with an average water depth of approximately 4 feet MLLW. Surface sediments are characterized by relatively high TOC (2.74%), bulk density of about 1.4 g/cm³, and an average moisture content of 53.6%. The Surface area weighted average concentration (SWAC) for total PCBs in the DU is 938 µg/kg and the maximum concentration of 4,200 µg/kg is located in the area east of the groin at east of the groin (US Navy, 2015).

5.2.3.2 Potential Ongoing Sources

Potential contaminant sources in DU E-2 include point and non-point sources from surrounding commercial/industrial properties. Contaminant distribution data suggest that surface water runoff and/or the storm drain outfall associated with the Waiau Power Plant are the primary contaminant sources for DU E-2. Available evidence and contaminant distributions indicate that previous or current Navy activities have not contributed to the PCB contamination reported for this DU. However, recently, concerns have been raised with respect to potential historical releases from the former Waiau Drum Storage Facility site located to the east of DU E-2. Historical drawings and aerial photographs indicate the potential operation of an OWS at the southwest corner of the site (Figure 30). There is speculation that this OWS may have had a discharge path via a pipe leading southward into Pearl Harbor (Figure 22). There is no direct evidence for this pipeline, and its suspected presence is based on typical historical operational practices for similar OWS systems. Determining whether or not there is a likely hydrodynamic connectivity between the suspected outfall location and the contamination at DU E-2 will help to understand the potential influence of this suspected historical source area.

5.2.3.3 Transport and Distribution to Pearl Harbor

The sediment transport evaluation conducted as part of the Pearl Harbor RI/FS indicated that all areas within East Loch are depositional and that erosion is not likely to expose buried sediment. DU E-2 lies outside the maintenance dredging footprint, with limited ship traffic; therefore, sediments are not likely to be disturbed by dredging or propeller wash. However, strong discharge flows from the power plant outfall likely have the potential to resuspend sediments in the area on the eastern side of the groin.

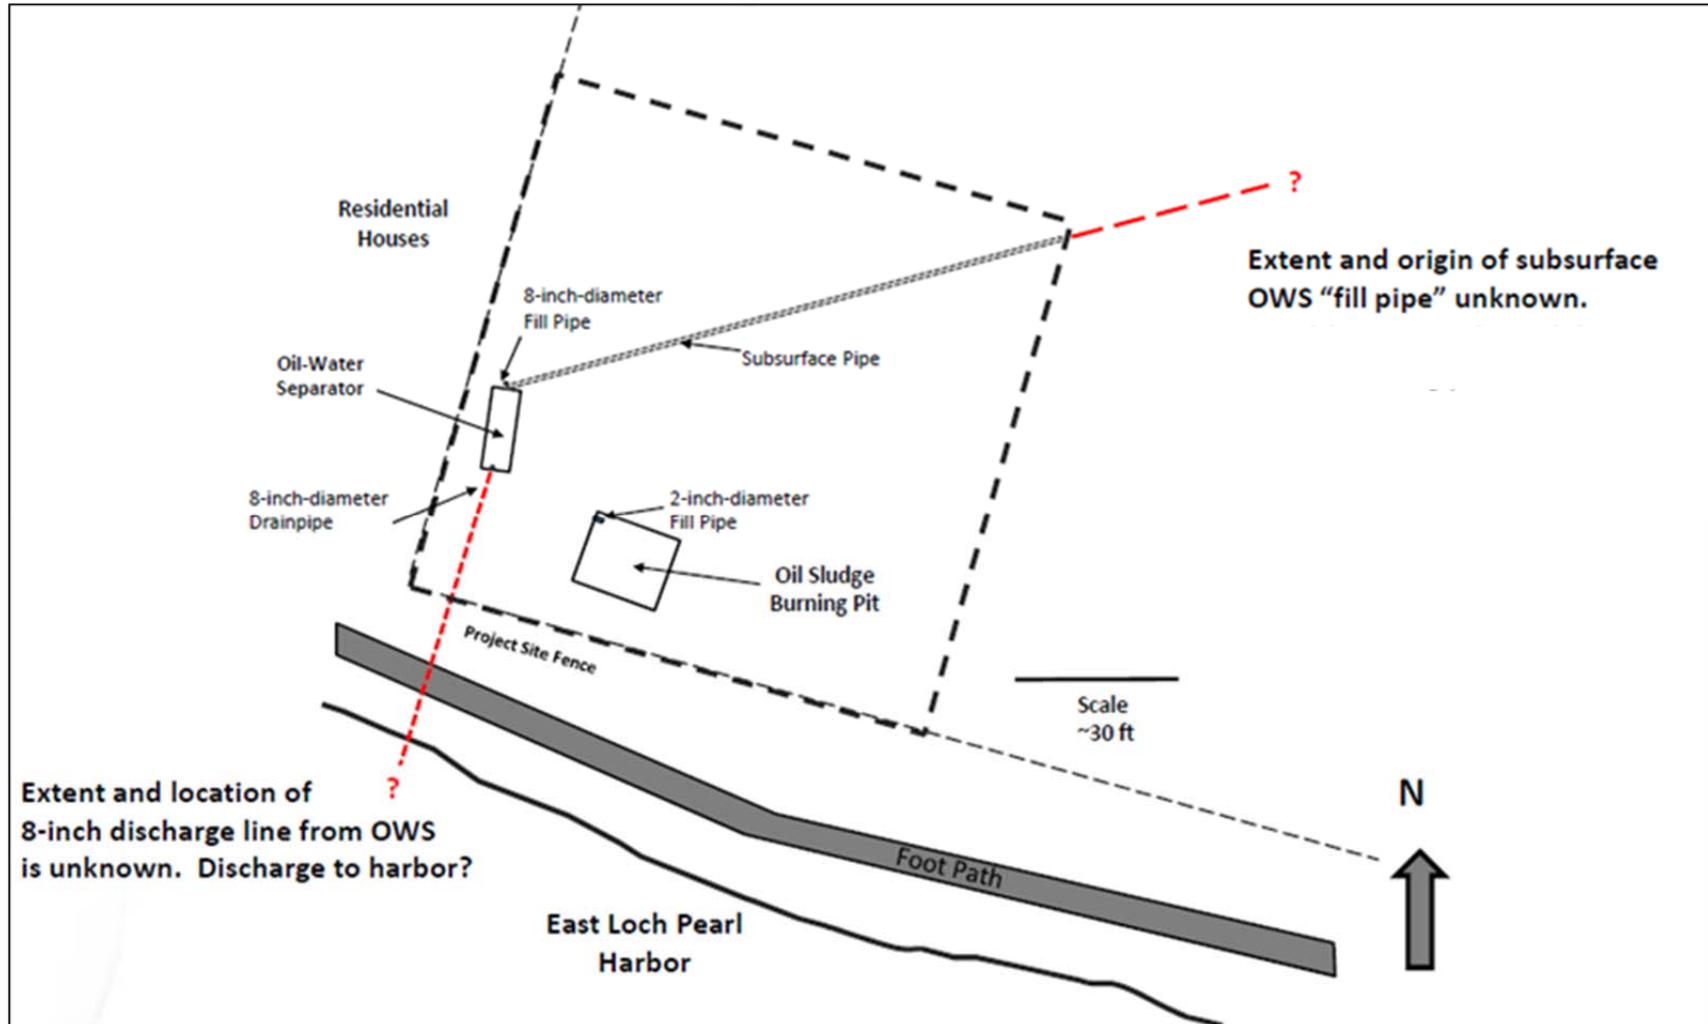

Figure 30. Schematic of the location of the OWS at the former drum storage facility (adapted from Hawaiian Electric, 2016).

5.3 Design and Layout of Technology Components

In this project, the technology components are represented by the three new technologies that are being adapted and demonstrated for the purpose of improved source and recontamination potential assessment. These included the DrEx system which was the focus of the first demonstration, and the DPS and SeDep systems which were the focus of the second demonstration. The basic design and layout of these components is described for each of the demonstrations below.

5.3.1 Naval Base San Diego – Paleta Creek

For the demonstration at the mouth of Paleta Creek, the stormwater discharge emerges from the creek mouth into San Diego Bay in a protected area within the piers at NBSD (termed the inner creek mouth). The discharge from the creek is flashy and responds relatively quickly to precipitation events in the Paleta Creek watershed (Figure 31). Thus the layout for the demonstration focused on seeding the first flush discharge from the creek with a concentration of ~10 drifters within the confined portion of the inner creek mouth directly adjacent to the location where the creek enters the bay (Figure 23). Previous measurement and modeling studies during stormwater discharge events at the site suggested that the extent of the plume following discharge is generally limited to the area within the NBSD pier area for storm events of this typical magnitude (Figure 32). Thus the distribution of the drifters following release was expected to be generally within this area. The movement of the drifters was initially expected to be governed by the momentum of the discharge from the creek, which was expected to dissipate relatively quickly away from the discharge point at which time the transport would be dominated by tidal currents. Thus representative expected distributions of the drifters over time are as shown in the conceptual diagram of Figure 23.

5.3.2 Joint Base Pearl Harbor Hickam – Oscar Pier Area

For the demonstration at Oscar Pier JBPHH, the area of interest was along the pier face adjacent to the Pearl Harbor Entrance Channel. The tides in this area move primarily north and south along the channel during the flood and ebb tide, respectively. Thus the layout for the first phase of the demonstration was to release groups of DPS units in the vicinity of a selected outfall along Oscar Pier during different stages of the tide. The bottom contact locations for the DPS units were then used to define the deposition footprint for particles linked to the outfall location (Figure 24). The footprint defined from this phase was then used to establish the layout of the SeDep units deployed in the next phase. These systems were left out over an extended period of time to evaluate the deposition associated with multiple stormwater discharge events.

5.3.3 Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area

For the demonstration at the Waiiau Power Plant area in JBPHH, the area of interest was in East Loch offshore from the former drum storage site and OWS. The tides in this area move primarily east and west along the channel during the flood and ebb tide, respectively. Thus the layout for the demonstration was to release groups of DPS units in the vicinity of the suspected outfall location during different stages of the tide. The bottom contact locations for the DPS units were then used to define the deposition footprint for particles linked to the outfall location (Figure 25).

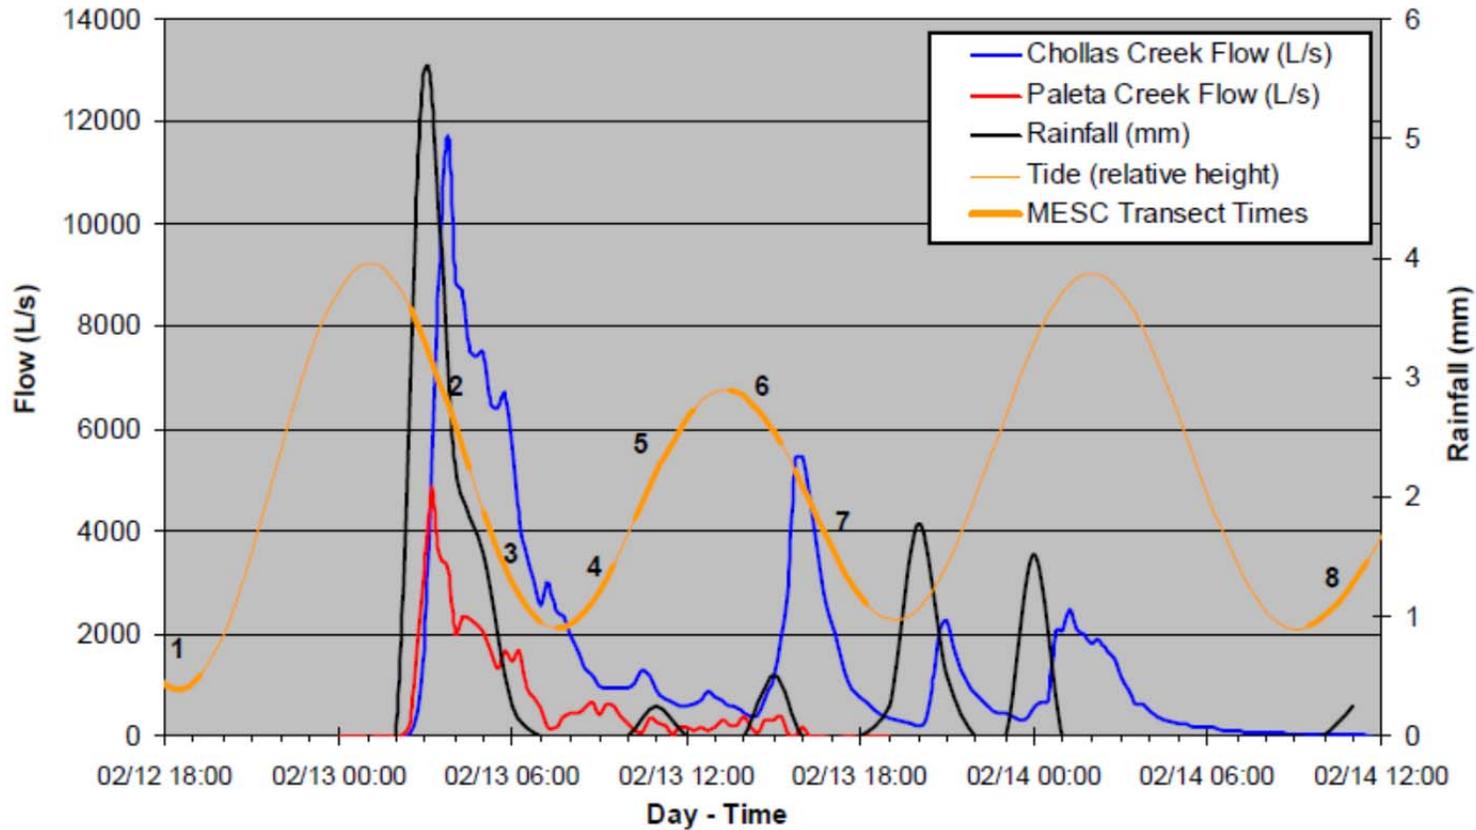

Figure 31. Precipitation (black line) and flow (red line) for Paleta Creek a significant storm event (>0.5 in) during February 2001. Note the rapid response of the creek flow to the precipitation event with peak flow lagging peak precipitation by less than one hour (Chadwick et al., 2002).

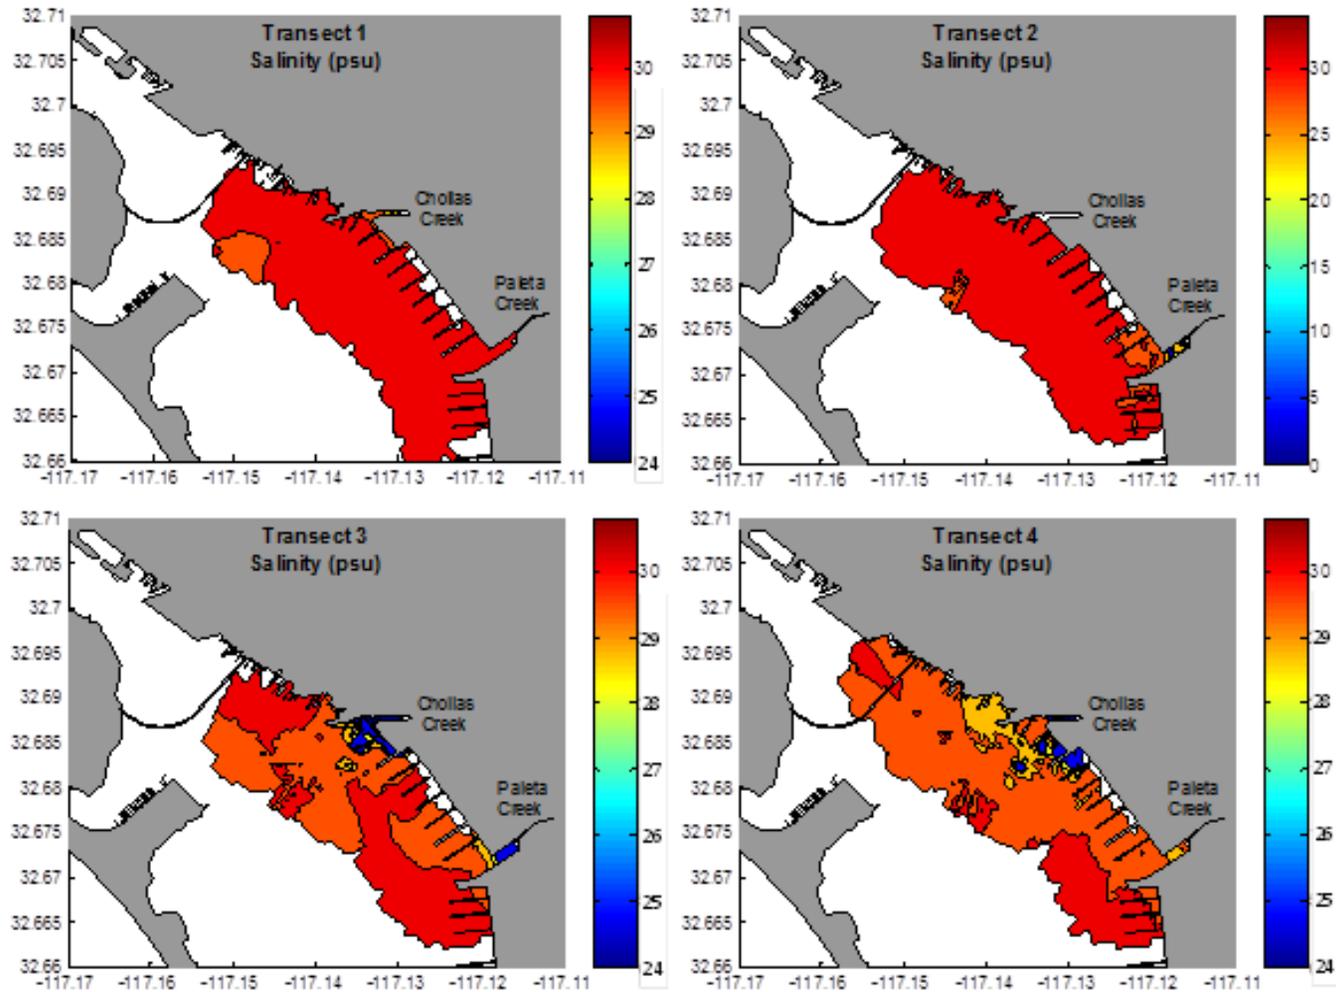

Figure 32. Salinity distribution before (Transect 1) and during the February 2001 storm event (Chadwick et al., 2002).

5.4 Field Testing

Field testing for these technologies was the primary focus of the demonstration project. Testing the systems in the field under realistic operational conditions provided the best opportunity to understand their utility and gauge their performance. The field testing approach for each of the demonstrations is described in detail below.

5.4.1 Naval Base San Diego – Paleta Creek

The field testing approach for the DrEx demonstration at Paleta Creek included several components including pre-deployment preparation, DrEx deployments, DrEx tracking, DrEx sampling, performance verification measurements, DrEx retrieval, and post-retrieval processing. Subsequent sample and data analysis are described in the following section. Field related components are described below.

5.4.1.1 Preparation

Preparation of the DrEx systems included a number of steps that were detailed in the draft manual for the system (see the project Demonstration Plan). These steps consisted of physical preparation, testing, and programming. Physical preparation included preparation of 121 drifter, the PAWS water sampling system, and any ancillary sensor or systems that were planned for use with the drifter. The physical preparation of the 121 drifter included opening up the main unit, installation of fresh batteries, re-sealing of the unit, installation of the sails, installation of the floats, and attachment of any lights, reflectors, or flags that were being used for visual tracking and collision avoidance. Physical preparation of the PAWS included starting with all pre-cleaned tubing and components for the water sampling system, opening up the unit, installing the tubing, installing the sampling bag, installing the inlet screen, and re-sealing the unit. The PAWS was then attached to the main hull of the 121 drifter with its mounting bracket, and the power/communication cable was attached. Detailed instructions are included in the manual.

System testing for the DrEx included testing of the GPS, communications, and pumping systems. To test the GPS and communications, the system was placed outdoors in an area not significantly blocked by buildings. A laptop was connected to the communications port on the antenna, and the tracking system was programmed to start with the update rate set to its minimum interval of 30 seconds. The system was then activated with the magnetic switch on the main hull. Using the Brightwaters data distribution website, the communications and GPS operation were then verified. Using the laptop, the functioning of the water sampling system was then tested to verify pump operation.

Programming of the DrEx system included inputting settings for the GPS sampling rate, the communications transmission rate, and several pump settings that are deployment specific. For short-term deployments associated with stormwater discharges, the GPS sampling rate was generally set to its minimum interval of 15 seconds to maximize the spatial resolution of the trajectory measurements. The communication interval was set to 5 minutes in order to keep track of the system, address any issues, and efficiently retrieve the unit. Pump settings depended on the desired sample volume and compositing period and were specific to each unit based on pump calibrations.

5.4.1.2 Deployment

Once the system was setup, tested and programmed, it was ready for deployment. Deployments for this demonstration were targeted to first-flush stormwater conditions at the discharge of Paleta Creek to San Diego Bay. In San Diego, precipitation driven stormwater discharge events are most frequent during the winter months from November through April (Figure 33). For logistical purposes, we originally targeted early season storms so that we could also conduct the second demonstration during the rainy season in Pearl Harbor. However, storms in the early part of the season were limited and thus the deployments took place in the January-February timeframe. The deployments were planned to occur during the first flush (~30 minutes) of two storm events during this window. Once the drifters were prepared, deployment involved loading the units onto the survey boat, transiting to the deployment location at the mouth of Paleta Creek, and releasing the units within the observed discharge plume emerging from the creek. Our plan was to track incoming weather systems and mobilize to the deployment area ahead of time based on predictions of rainfall >0.2 inches with a >70% probability within 24 hours of the event. The survey boat was loaded with the drifters and other required equipment and moored at the small boat pier in the Paleta Creek mouth area (Figure 34). Approximately six hours ahead of the event, the crew mobilized to the boat and remained on standby for the deployment. Within the first-flush time window, the boat transited the short distance to the discharge area, and the drifters were released into the turbid, low-salinity waters of the plume zone (Figure 35).

5.4.1.3 Tracking

Following the release of the drifters, the systems were tracked to observe their trajectories, verify operation, and identify and rectify any problems as they transited with the stormwater plume from Paleta Creek (Figure 36). Tracking was performed with a cellular hot-spot installed on the survey boat, allowing internet access to the Brightwaters web-access portal (Figure 37). This allowed real-time monitoring of the positions and water sampling progress. At regular intervals throughout the survey, each DrEx unit was revisited to check on its performance and conduct performance verification measurements as described in the next section. Tracks were uploaded and plotted on using a MatLab routine to allow visual analysis of the trajectories over time. In cases where systems become snagged on the piers, shorelines, or other obstacles, intervention was performed to return the unit to free drifting conditions. In instances where the drifter could potentially interfere with NBSD operations or result in an unsafe condition, NBSD personnel were contacted and corrective actions were taken as necessary to insure safety and no impact to operations. In instances where a unit stopped functioning, efforts were made to locate the unit, diagnose the problem, and either return it to use or document the problem and remove it from operation. The tracking period extended over a 6-12 hour period or until the plume has significantly dissipated based on measured salinity and turbidity in the surface waters in the vicinity of the drifters.

5.4.1.4 Performance Verification

During the field demonstration, a range of performance verification measures were conducted. Performance of the DrEx system was gauged for key quantitative and qualitative performance metrics. For tracking, these metrics included measures of the accuracy achieved by the GPS units, the reliability of the communications link, the survivability of the units, and the ability to maintain tracking of the surface plume. GPS accuracy was automatically recorded by the units and was also compared to a high-precision sub-meter resolution GPS unit that was held

alongside the drifter GPS at various intervals during the trajectories (Figure 38). Reliability of the communications link was measured based on the percent of time that the communications link was maintained during the survey period. The survivability of the units was determined by the percent of units that successfully complete the mission, accounting for units that were lost, disabled, malfunctioned, etc. The ability to maintain tracking of the plume was evaluated based on measures including the onboard temperature and salinity recorder, and by comparing the drifter trajectory to plume mapping that was carried out simultaneously from the survey boat. For sampling, performance was evaluated based on successful collection of target sample volumes over the prescribed time interval. Performance metrics and measures are summarized in Table 4.

5.4.1.5 Retrieval

At the end of the field survey, the DrEx units were located using the real-time monitoring and retrieved to the survey boat. Samples were removed from the PAWS units for processing, and data were downloaded from the onboard temperature and salinity sensors. Each unit was inspected for any physical damage, and a series of tests were run to verify that all aspects of the operation were still functional. Any issues or deficiencies were documented. The system was then cleaned, disassembled and stowed in accordance with demobilization procedures and the system manuals.

5.4.2 Joint Base Pearl Harbor Hickam – Oscar Pier Area

The field testing approach for the DPS and SeDep demonstration at Pearl Harbor Oscar Pier included a two-phase approach. In the first phase, DPS units were deployed to map the deposition footprint associated with a selected outfall at Oscar pier. This phase involve multiple components including pre-deployment preparation, DPS deployments, DPS tracking, performance verification measurements, and DPS retrieval. In the second phase, SeDep systems were deployed to monitor deposition events within the footprint defined by the DPS units. This phase involved pre-deployment preparation, SeDep deployments, performance verification measurements, and SeDep retrieval. The field testing approach for these two phases is described below.

5.4.2.1 Phase 1 - DPS Deposition Footprint Mapping

In this phase, DPS units were deployed to map the deposition footprint associated with a selected outfall at Oscar pier. This phase involved multiple components including pre-deployment preparation, DPS deployments, DPS tracking, performance verification measurements, and DPS retrieval.

Preparation: Preparation of the DPS systems included a number of steps that are detailed in the project demonstration plan. These steps consisted of physical preparation, testing, and programming (Figure 39). Physical preparation included preparation of Microstar drifter, the winch system, and the ancillary sensors and systems that were planned for use with the drifter. The physical preparation of the Microstar drifter included opening up the main unit, installation of fresh batteries, re-sealing of the unit, preparation of the drogue, connection of the winch, and charging of the lights that were used for visual tracking and collision avoidance. Physical preparation of the winch included charging of the batteries, winding on the line, mounting the winch in the central hull, mounting the central hull in the drogue, setting the bottom detection sensor depth, and attaching the winch line to the GPS float. Detailed instructions are included in the manual.

System testing included testing of the GPS, communications, and winch systems. To test the GPS and communications, the system was placed outdoors in an area not significantly blocked by buildings. A laptop was connected to the internet and the logged in to the Pacific Gyre web-access portal. Commands were transmitted over the Iridium communications link to program the test conditions for the drifter. The output from the drifter was then monitored over the communications link to verify communications and check that the GPS positioning was working properly. To test the winch operations, the laptop was connected to the winch via the external connector on the winch. Program commands were then sent to the winch to test the communications and operations. Once the drifter and winch had been tested, they were ready for final pre-deployment programming.

Programming of the DPS drifter system included inputting settings for the GPS sampling rate and the communications transmission rate. For short-term deployments associated with stormwater discharges, the GPS sampling rate was generally set to its minimum interval of 2 seconds to maximize the spatial resolution of the trajectory measurements. The communication interval was set to 5 minutes in order to keep track of the system, address any issues, and efficiently retrieve the unit. The winch was programmed independently of the drifter. The primary winch setting was the settling velocity. This value is dependent on the effective settling rate of the particles that are being simulated. A table of typical in situ settling rates is shown in

Table 7. For example, a recent review of effective particle settling rates for estuarine conditions suggests rates ranging from about 0.1 – 10 mm/s (Shi and Zhou, 2004), while coarser particles that might be associated with high energy stormwater runoff events could settle at higher rates in the range of 50-100 mm/s (Droppo, 2006). Given typical DoD harbor depths of 10 m, this translates into transit times ranging from about 5 minutes to 1 day.

For the case of Pearl Harbor Oscar Pier, there was limited specific characterization data for the outfall discharge particle composition. Instead, we based our particle characteristics on the character of surface sediments in the vicinity of the outfall. For the area of interest, particle size of surface sediments was observed in the sand (~41%), silt (~41%), and clay (~16%) size classes (U.S. Navy, 2015). Given the predominance of silt, we focused on this fraction. Sand sized particles are likely to settle close the outfall, and clay sized particles are very widely distributed by transport. Silt sized particles often carry a much more significant portion of the contaminant load compared to sand. Assuming a typical silt sized particle of 10 um, we used Cheng's formula (Cheng, 1997) to estimate a typical settling rate of about 0.56 mm/s or 34 mm/min. This settling velocity was used for all of the DPS units. For 10 m of water depth which is typical for the area, this results in a transit time of about 6 hours.

Deployment: Deployments for the Phase 1 field testing of the DPS were spread out across the tidal cycle so that we captured the overall extent of the potential deposition zone that is linked to the outfall. We also targeted relatively large amplitude (spring) tide conditions which captured the maximum transport range for particles from the outfall area. We deployed DPS units at approximately 1-1.5 hour intervals throughout varying tidal conditions including slack ebb, mid flood, slack flood, and mid ebb. Because we only had access to 10 systems, the drifters were retrieved after they made bottom contact, the data were downloaded and the battery charged, and then the units were re-released to capture the other target release times. To minimize operational impacts, these deployments were timed to occur on the weekend when the operational tempo was lower. The deployment location was targeted for an outfall at the southeast end of the Oscar Pier area that faced the main navigation channel (Figure 40). Areas of potential concern from an ongoing source perspective are located along this area.

Tracking: Following the release of the drifters, the systems were tracked to observe their trajectories, verify operation, and identify and rectify any problems along the transit paths (Figure 41). Tracking was performed with a cellular hot-spot installed on the survey boat, allowing internet access to the Pacific Gyre web-access portal. This allowed for real-time monitoring of the positions and water sampling progress. At regular intervals throughout the survey, each DPS unit was revisited to check on its performance and conduct performance verification measurements as described in the next section. Tracks were uploaded and plotted on GoogleEarth® to allow visual analysis of the trajectories over time. In cases where systems became snagged on the piers, shorelines, or other obstacles, intervention was performed to return the unit to free drifting conditions. In instances where the drifter could have potentially interfered with JBPHH operations, JBPHH personnel were contacted and corrective actions were taken as necessary to insure safety and no impact to operations. In instances where a unit stopped functioning, efforts were made to locate the unit, diagnose the problem, and either return it to use or document the problem and remove it from operation.

Performance Verification: During the Phase 1 DPS deployments, a range of performance verification measures were taken. For the DPS system, we established a series of quantitative and qualitative performance objectives similar to the DrEx but adapted to the particle tracking

capability of the system. GPS accuracy was automatically recorded by the units and was also compared to a high-precision sub-meter resolution GPS unit that was held alongside the drifter GPS at various intervals during the trajectories (Figure 42). During these position checks, water depths were also measured for post-survey comparison to the pressure sensor on the DPS to verify that the bottom detection system was performing properly. Reliability of the communications link was measured based on the percent of time that the communications link was maintained during the survey period. The survivability of the units was determined by the percent of units that successfully completed the mission, accounting for units that were lost, disabled, malfunctioned, etc. An important aspect of the DPS system is its ability to simulate the effective rate of settling for discharge related particles during the deployment period. Reliable settling rates were monitored using the depth data from pressure sensor onboard DPS. In addition, reel-up times were recorded to determine if they corresponded to the relatively predictable deployment periods based on the programmed settling rate and the water depth at the point of bottom contact.

Retrieval: At the end of the field survey, the DPS units were located using the real-time monitoring and retrieved to the survey boat. The deposition cycle of the drifter was confirmed by observing that the drogue was back at the surface. Data were then downloaded from each unit including the high-resolution GPS and pressure data that define the trajectory, and the bottom detection information from the tilt sensor. Each unit was inspected for any physical damage, and a series of tests were run to verify that all aspects of the operation were still functional. Any issues or deficiencies were documented. The systems were then cleaned, disassembled and stowed in accordance with demobilization procedures and the system manuals.

5.4.2.2 Phase 2: SeDep Deposition Monitoring

In the second phase, SeDep systems (Figure 43) were deployed to monitor deposition events within the footprint defined by the DPS units. This phase involved pre-deployment preparation, SeDep deployments, performance verification measurements, and SeDep retrieval.

Preparation: Preparation of the SeDep systems included the setup, testing and programming of the sensors, and the preparation of the sediment traps. Setup of the sensors involved opening the pressure housing, installing new batteries, re-sealing the housing, pre-filling the pressure plate and plumbing with water and purging any residual air, and closing the pressure plate valves as described in the manual (Figure 44). Testing the systems was done by connecting a laptop and monitoring the pressure sensor, opening the valves with the unit submersed in still water, and placing one of the calibration mats (1/8 inch rubber) on the pressure plate to make sure the system was responding as expected. After completing, the valves were reclosed and the system was kept submersed. Programming the system involved clearing and data from memory, setting the sampling interval, and setting the start time for data recording. Preparing the sediment traps required cleaning the interior, exterior, mesh and caps, securing the mesh over the top, filling the trap ~2/3 full of brine solution, and covering with the cap. After the traps were prepared, they were placed in a rack that held them vertically in preparation for deployment.

Deployment: Deployment of the SeDep system was performed by diver. Deployment locations were based on DPS measurements to identify the locations of interest. The procedure required first installing the sediment trap (Figure 45), then installing the SeDep sensor, then mounting the data logger to the sediment trap stake. Installation of the pressure sensor was done by taking the system from the boat down to the sediment surface with the valves open. At the bottom, the system was gently manipulated to make sure any residual air bubbles were out, and then the valves were closed. The flat pressure plate was then gently inserted into the sediment to a depth of about 7.5 cm using the stainless steel handles. The pressure plate was aligned so that the plate was flat (horizontal) with the flexible side pointing up. Care was taken to minimize sediment disturbance, damage to the flexible membrane, and to assure that the system was as level as possible. The burial depth was then confirmed with a ruler. Any disturbance to the sediment was carefully smoothed out.

The cable and data logger were then be moved to a distance about 2 meters away from the sensor where the sediment trap was installed. The data logger was mounted to the vertical stake that held the sediment trap at about mid-level with the cable running out the bottom into the sediment (Figure 46). The sediment trap cap was then removed and the deployment was complete.

Performance Verification: During the Phase 2 SeDep deployments, performance verification measures focused on deposition detection sensitivity, measurement reliability, system survivability, and ease of use. Detection sensitivity was evaluated primarily under controlled lab conditions prior to deployment, but was also assessed during field measurements based on the variability measured during quiescent periods of the deployment when no storm events, ship movements or other significant sediment transport processes were active. Measurement reliability was evaluated using the completeness of the differential pressure data from field deployments. Survivability in the field was evaluated based on successful mission completion, without major system failures or lost units during field deployments. Ease of use was evaluated based on feedback from the dive team.

Retrieval: The SeDep systems were deployed for an extended period of 1-2 months to capture deposition associated with multiple runoff events. Following that period, divers were deployed to retrieve the units. This involved first capping the sediment trap (to minimize any diver resuspension effects during the retrieval), collecting a shallow, undisturbed core from above the pressure plate, and then retrieving all of the equipment to the survey boat. Following retrieval, data were downloaded from the pressure sensor data loggers, the trap and core samples were processed for analysis, each unit was inspected for any physical damage, and a series of tests were run to verify that all aspects of the operation were still functional. The systems was then cleaned, disassembled and stowed in accordance with demobilization procedures and the system manuals.

5.4.3 Joint Base Pearl Harbor Hickam – Waiiau Power Plant Area

The field testing approach for the second DPS demonstration at Pearl Harbor focused on DPS mapping of the potential deposition footprint from a suspected historical Navy oil-water separator outfall believed to have been located at the current site of Neal S Blaisdell Park in Honolulu, HI, on the northern shore of East Loch in Pearl Harbor just east of the Waiiau Generating Station (Figure 47). DPS units were deployed to map the deposition footprint associated with a suspected oil-water separator outfall along the western boundary of what was once a Navy drum storage yard and is now the park. This involved multiple components including pre-deployment preparation, DPS deployments, DPS tracking, performance verification measurements, and DPS retrieval. The field testing approach is described below.

5.4.3.1 DPS Deposition Footprint Mapping

DPS units were deployed to map the deposition footprint associated with the suspected oil-water separator outfall off the Waiiau area. This involved multiple components including pre-deployment preparation, DPS deployments, DPS tracking, performance verification measurements, and DPS retrieval. Because the site is very shallow, the drogues for the DPS units were modified to reduce their vertical profile dimension to about 24” (Figure 48). This allowed for operation in the shallow waters off of the park area.

Preparation: Preparation of the DPS systems included a number of steps that are detailed in the draft manual for the system. These steps consisted of physical preparation, testing, and programming. Physical preparation included preparation of Microstar drifter, the winch system, and the ancillary sensors that were planned for use with the drifter. The physical preparation of the Microstar drifter included opening up the main unit, installation of fresh batteries, re-sealing of the unit, preparation of the drogue, and connection of the winch. Physical preparation of the winch included charging of the batteries, winding on the line, mounting the winch in the central hull, mounting the central hull in the drogue, setting the bottom detection sensor depth, and attaching the winch line to the GPS float. Detailed instructions are included in the manual. The system was then ready for testing and programming.

System testing included testing of the GPS, communications, and winch systems. To test the GPS and communications, the system was placed outdoors in an area not significantly blocked by buildings. A laptop was connected to the internet and the logged in to the Pacific Gyre web-access portal. Commands were transmitted over the Iridium communications link to program the test conditions for the drifter. The output from the drifter was then monitored over the communications link to verify communications and check that the GPS positioning was working properly. To test the winch operations, the laptop was connected to the winch via the external connector on the winch. Program commands were then sent to the winch to test the communications and operations (Figure 49). Once the drifter and winch were tested, they were ready for final pre-deployment programming.

Programming of the DPS drifter system included inputting settings for the GPS sampling rate and the communications transmission rate. For these short-term deployments associated shallow water particle tracking simulations, the GPS sampling rate was set to its minimum interval to maximize the spatial resolution of the trajectory measurements. The communication interval was set to 5 minutes in order to keep track of the system, address any issues, and efficiently retrieve the unit. The winch was programmed independently of the drifter. The primary winch setting was the settling velocity. This value is dependent on the effective settling rate of the particles

that are being simulated. A table of typical in situ settling rates is shown in Table 7. For example, a recent review of effective particle settling rates for estuarine conditions suggests rates ranging from about 0.1 – 10 mm/s (Shi and Zhou, 2004), while coarser particles that might be associated with high energy stormwater runoff events could settle at higher rates in the range of 50-100 mm/s (Droppo, 2006). Given typical DoD harbor depths of 10 m, this translates into transit times ranging from about 5 minutes to 1 day.

For the case of this suspected outfall in Pearl Harbor, there was no characterization data for the outfall discharge particle composition. For the area of interest, particle size of surface sediments was observed in the sand (~40%), silt (~45%), and clay (~15%) size classes, very similar to the previous site demonstration at Oscar Pier (U.S. Navy, 2015). Given the predominance of silt, we focused on this fraction. Sand sized particles are likely to settle close the outfall, and clay sized particles are very widely distributed by transport. Silt sized particles often carry a much more significant portion of the contaminant load compared to sand. Assuming a typical silt sized particle of 10 μm , we used Cheng's formula (Cheng, 1997) to estimate a typical settling rate of about 0.56 mm/s or 34 mm/min. This settling velocity was used for all of the DPS units. For 4-10 m of water depth which is typical for the area, this results in a transit time of about 2-5 hours.

Deployment: Deployments for the field testing of the DPS were spread out across the tidal cycle so that we could capture the overall extent of the potential deposition zone that was linked to the outfall. We also targeted relatively large amplitude (spring) tide conditions which captured the maximum transport range for particles from the outfall area. We deployed individual DPS units on an ~hourly schedule through a complete tidal cycle. Because we only had access to 10 systems, these releases took place by releasing and then retrieving DPS units as they made bottom contact, and then re-releasing them up to three times. An example is shown in Figure 50. To minimize operational impacts, these deployments were timed to occur on the weekend when the operational tempo was lower. The deployment location was targeted to a location corresponding to the suspected outfall, and far enough offshore to have a depth of at least 1.5 m.

Tracking: Following the release of the drifters, the systems were tracked to observe their trajectories, verify operation, and identify and rectify any problems. Tracking was performed with a cellular hot-spot installed on the survey boat, allowing internet access to the Pacific Gyre web-access portal. This allowed for real-time monitoring of the positions. At regular intervals throughout the survey, each DPS unit was revisited to check on its performance and conduct performance verification measurements as described in the next section. Tracks were uploaded and plotted on GoogleEarth® to allow visual analysis of the trajectories over time. In cases where systems became snagged on the piers, shorelines, or other obstacles, intervention was performed to return the unit to free drifting conditions. In instances where the drifter could have potentially interfered with JBPHH operations, JBPHH personnel were contacted and corrective actions were taken as necessary to insure safety and no impact to operations. In instances where a unit stopped functioning, efforts were made to locate the unit, diagnose the problem, and either return it to use or document the problem and remove it from operation.

Performance Verification: During the Phase 1 DPS deployments, a range of performance verification measures were taken. For the DPS system, we established a series of quantitative and qualitative performance objectives similar to the DrEx but adapted to the particle tracking capability of the system. GPS accuracy was automatically recorded by the units and was also compared to a high-precision sub-meter resolution GPS unit that was held alongside the drifter GPS at various intervals during the trajectories. During these position checks, water depths were

also measured for post-survey comparison to the pressure sensor on the DPS to verify that the bottom detection system was performing properly. Reliability of the communications link was measured based on the percent of time that the communications link was maintained during the survey period. The survivability of the units was determined by the percent of units that successfully completed the mission, accounting for units that were lost, disabled, malfunctioned, etc. An important aspect of the DPS system is its ability to simulate the effective rate of settling for discharge related particles during the deployment period. Reliable settling rates were monitored using the depth data from pressure sensor onboard DPS. In addition, reel-up times monitored to see if they corresponded to relatively predictable deployment periods based on the programmed settling rate and the water depth at the point of bottom contact.

Retrieval: At the end of the field survey, the DPS units were located using the real-time monitoring and retrieved to the survey boat. The deposition cycle of the drifter was confirmed by observing that the drogue was back at the surface. Data were downloaded from each unit including the high-resolution GPS and pressure data that defined the trajectory, and the bottom detection information from the tilt sensor. Each unit was inspected for any physical damage, and a series of tests were run to verify that all aspects of the operation were still functional. Any issues or deficiencies were documented. The systems were then cleaned, disassembled and stowed in accordance with demobilization procedures and the system manuals.

5.5 Sampling Plan

This demonstration incorporated sensor measurements, water, and sampling into both direct aspects of the technologies being demonstrated, as well as the validation measures that were employed. Descriptions of the sampling plans for each of the demonstrations are provided below.

5.5.1 Naval Base San Diego – Paleta Creek

As outlined in the field testing description above, the demonstration at NBSD focused on demonstration and validation of the DrEx system for monitoring the transport, exposure and fate of stormwater plumes. The DrEx system incorporates a range of sensor and water sampling capabilities including positioning, temperature, salinity, pump status, composite samples and passive samples. In addition, verification measurements and sampling were part of the demonstration to quantify the performance of the system relative to established metrics. These two lines of sampling are described below.

5.5.1.1 DrEx Sensor Measurements and Sampling

The DrEx system incorporates a range of sensor and water sampling capabilities including positioning, temperature, salinity, pump status, composite samples and passive samples. The system provides a significant amount of flexibility in how these measurement and samples are collected so that site specific conditions can be accommodated. For this demonstration, we were focused on characterizing the transport and exposure associated with the discharge of stormwater from an urban/industrial creek into a coastal harbor. We recorded sensor measurements from the GPS and a temperature/salinity logger attached to the drifter, along with monitoring the pump status (Table 8). These data were collected throughout the deployment at a rate of about one measurement per minute. Composite samples and passive samples were collected from the drifters (Table 8). Each drifter collected one composite sample and was fitted with metal and organic passive samplers. The composite samplers ran at a sampling rate of about 2-3 ml/min to provide a total of about 2-3 liters of sample over the 6-12 hour deployment. The DGT sampler for the metals sampled passively from a location attached to the drifter hull. The SPME sampler for the organics was housed in a Teflon tube with an independent pump to enhance the flow rate which ran continuously during the deployment. Composite samples were analyzed for metals, organics, TSS and toxicity. Baseline data and previous stormwater monitoring guided us to include copper, lead and zinc for metals analysis. Organics of interest included PAHs, PCBs and chlorinated pesticides. Toxicity endpoints targeted chronic endpoints of embryo larval development for the mussel *Mytilus galloprovincialis* and/or the sea urchin *Strongylocentrotus purpuratus*. DGT samples were analyzed for the same metals including copper, lead, and zinc, and SPME samples targeted the same organic analytes at the composite samples.

5.5.1.2 DrEx Performance Verification Sensor Measurements and Sampling

Additional measurements and sampling were carried out as part of the performance verification for the DrEx. A high-precision sub-meter resolution GPS unit was held alongside the drifter GPS at various intervals during the trajectories to verify the onboard GPS performance. Plume mapping was carried out from the survey boat using a towed Conductivity, Temperature and Depth (CTD) system (Chadwick and Salazar, 1991) to verify the tracking of the plume by the drifters. Composite samples collected by the drifter were weighed before and after the event to

verify the operation of the pumping system. Verification sampling measures are summarized in Table 10.

5.5.1.3 Quality Control

Quality control methods including calibrations, decontamination procedures, quality assurance sampling, and sample documentation for the DrEx demonstration are described below.

Calibration of Analytical Equipment. Equipment requiring calibration for the demonstration included the composite sampling pump on the PAWS, the conductivity sensor on the drifter, and the conductivity sensor used for the verification mapping. The PAWS pump was calibrated by programming it to pump at different rates within the expected range for a set period of time and measuring the amount of volume pumped with a graduated cylinder. Results from this calibration were applied to the raw pump cycle data to convert it to volume. The conductivity sensors were calibrated with National Institute of Standards (NIST) standards over the range of expected values for the field study. The range for the field study was expected to be between freshwater (< 1 mS/cm) and seawater (>45 mS/cm). A three point calibration was performed using standards within this range. Analytical equipment was calibrated in accordance with the standard methods for the analysis of interest.

Quality Assurance Sampling. Quality assurance sampling included field duplicates, matrix spike and matrix spike duplicates (MS/MSD), and equipment blanks. Field duplicates, MS/MSDs, and equipment blanks were collected at a rate of one per ten field samples.

Decontamination Procedures. Decontamination procedures focused on proper preparation of sampling equipment prior to the sampling events. These procedures were generally in accordance with the standard operating procedures for the sampling and analysis methods defined for the project.

Sample Documentation. Sampling documentation included electronic records, sample labels, custody seals, field logbooks, log sheets, photographs, chain-of-custody forms, and laboratory logbooks.

Table 8. Total numbers and types of samples for the DrEx demonstration at NBSD.

| Sensor/Sampler | Source | Sampled Via | Data Parameters | Planned Sampling Rate | Expected Number of Samples |
|------------------------------|---|--|---|-----------------------|----------------------------|
| GPS | Brightwaters 121 Drifter | Iridium Modem & Post-Survey Download | Serial number, record number, data, time, GPS status, GPS wakeup time, GPS latitude, GPS longitude, External power (on or off), battery level | 1/min | 1440 per 24 hours |
| Pump Data | Brightwaters 127 PAWS | Iridium Modem & Post-Survey Download | Pump state, pump direction, volume count, internal humidity, minimum volume count, maximum volume count | 1/min | 1440 per 24 hours |
| Temperature | HOBO Conductivity/Salinity Data Logger U24-002-C mounted on drifter | Post-Survey Download | Date, time, temperature, conductivity | 1/min | 1440 per 24 hours |
| Salinity | HOBO Conductivity/Salinity Data Logger U24-002-C mounted on drifter | Post-Survey Download | Date, time, temperature, conductivity | 1/min | 1440 per 24 hours |
| Upstream Grab Sample | Dipper or Isco Sampler | Grab during first flush | Metals, organics, TSS, DOC and toxicity | Grab | 1 per event |
| DrEx Composite Sample | Brightwaters 127 PAWS | Continuous pump collection during survey | Metals, organics, TSS, DOC and toxicity | ~2-3 ml/min | 1 per drifter |
| DrEx Passive Metals Sample | DGT disc samplers mounted on drifter | Continuous passive collection during survey | Dissolved metals | N/A | 2 per drifter |
| DrEx Passive Organics Sample | SPME fibers in Teflon tube mounted on drifter | Continuous pumped/passive collection during survey | Dissolved organics | N/A | 1 per drifter |

| GPS | Trimble GeoXH | Survey boat positioned at drifter | Date, Time, GPS latitude, GPS longitude, GPS precision | 1/hour | 24/day |
| Towed CTD | Seabird conductivity, temperature, and depth profiler (CTD), outfitted with pH probe and dissolved oxygen sensor, and a SeaTech light transmissometer | Towed V-fin adjacent to survey boat | Surface water temperature, salinity, pH, dissolved oxygen, and light transmission | 1/sec | 1 transect through the plume area every 2 hours |
| Sample Volume | Mettler PE22 Precision Electronic Balance | Pre- and Post-Survey weights | Sample volume | One per sample per survey | 10/survey |

5.5.2 Joint Base Pearl Harbor Hickam – Oscar Pier Area

As described in the field testing description above, the demonstration at JBPHH focused on demonstration and validation of the DPS and SeDep systems for monitoring the transport and deposition of stormwater associated particle plumes. The two systems incorporate a range of sensor and sampling capabilities including positioning, depth, bottom detection, deposition mass, and sediment trap accumulated sediments. In addition, verification measurements and sampling were part of the demonstration to quantify the performance of the systems relative to established metrics. These two lines of sampling are described below for each phase of the effort.

5.5.2.1 Phase 1 DPS Sensor Measurements

The DPS system incorporates a range of sensor capabilities but currently has no active sampling system. The primary purpose of these drifters is to identify deposition footprints for particles associated with outfalls and other discharges. Sensor measurements included positioning, temperature, salinity, depth and bottom detection. For this demonstration, we focused on characterizing the transport and fate of particles associated with the discharge of stormwater from an outfall into a coastal harbor. We recorded sensor measurements from the GPS, pressure sensor, bottom detector and a temperature/salinity logger attached to the drifter (Table 11). Position data were collected throughout the deployment at a rate of about one measurement per second and stored onboard the drifter. Position data were also telemetered via the Iridium modem about every 5 minutes. Depth measurements and line spool distance and bottom detection from the winch sensors were recorded every 30 seconds. Temperature and salinity data were also recorded every 30 seconds on the logger.

5.5.2.2 Phase 1 DPS Performance Verification Sensor Measurements

Additional measurements were carried out as part of the performance verification for the DPS. A high-precision sub-meter resolution GPS unit was held alongside the DPS surface float GPS at approximately one hour intervals during the trajectories to verify the onboard GPS performance. During these position checks, water depths were also measured for post-survey comparison to the pressure sensor on the DPS to verify that the bottom detection system was performing properly. Verification sampling measures are summarized in Table 13.

5.5.2.3 Phase 2 SeDep Sensor Measurements and Sampling

The SeDep system incorporates sensor and sediment sampling components. The sensor measurement records a time series of sediment mass on the deposition sensor, while the sediment trap collects an integrated sample of depositing sediment over time (Table 12). A surface sediment sample is also collected from above the deposition sensor at the end of the deployment period. For this demonstration, we were focused on characterizing the deposition of particles during stormwater runoff events in the vicinity of Oscar pier at JBPHH. We recorded deposition sensor measurements from the differential pressure sensor on the SeDep at a rate of about one measurement per minute. Corresponding time-integrated sediment trap samples were collected at SeDep stations representing the entire deployment period which was about 6 weeks. At the end of the deployment, surface sediment samples were collected from above the SeDep pressure sensor plates to further characterize deposited sediments. Sediment samples were characterized for contaminants of concern, grain size, TOC, and bulk density (Table 15). Chemical analysis included copper, lead, mercury and total PCBs, the key COCs for Southeast Loch.

5.5.2.4 Phase 2 SeDep Performance Verification Sensor Measurements

During the Phase 2 SeDep deployments, performance verification measures focused on deposition detection sensitivity, measurement reliability, system survivability, and ease of use. Detection sensitivity was evaluated during field measurements based on the variability measured during quiescent periods of the deployment when no storm events, ship movements or other significant sediment transport processes were active. These periods were identified based on direct observations during times when the field crew was on site, and also based on weather and operational data acquired from the site. In situ evaluation of the pressure sensor response was also attempted using calibration mats (rubber or vinyl sheeting) placed on top of the sensors by divers at the end of the deployment to check the in situ response to a known loading. These placements will be performed over approximately a one hour period (Table 14).

5.5.2.5 Quality Control

Quality control methods including calibrations, decontamination procedures, quality assurance sampling, and sample documentation for the DPS and SeDep demonstration are described below.

Calibration of Analytical Equipment. Equipment requiring calibration for the demonstration included the SeDep pressure sensor, and the conductivity sensor on the drifter. The SeDep pressure sensor was calibrated by submerging the unit in water and placing known weights on the pressure plate over the range of expected deposition. Results from this calibration were applied to the raw differential pressure data to convert it to mass. The conductivity sensors were calibrated with NIST standards over the range of expected values for the field study. The range for the field study is expected to be in the seawater range (~45 mS/cm). A three point calibration was performed using standards within this range. Analytical equipment was calibrated in accordance with the standard methods for the analysis of interest.

Quality Assurance Sampling. Quality assurance sampling included field duplicates, MS/MSDs, and equipment blanks. Field duplicates, MS/MSDs, and equipment blanks were collected at a rate of one per ten field samples.

Decontamination Procedures. Decontamination procedures focused on proper preparation of sampling equipment prior to the sampling events. These procedures were generally in accordance with the standard operating procedures for the sampling and analysis methods defined for the project.

Sample Documentation. Sampling documentation included electronic records, sample labels, custody seals, field logbooks, log sheets, photographs, chain-of-custody forms, and laboratory logbooks.

Table 11. Total numbers and types of samples for the Phase 1 DPS/SeDep demonstration at JBPHH.

| Sensor/Sampler | Source | Sampled Via | Data Parameters | Planned Sampling Rate | Expected Number of Samples |
|--------------------|---|--------------------------------------|--|--|----------------------------|
| Phase 1 DPS | | | | | |
| GPS | DPS Drifter Float | Iridium Modem & Post-Survey Download | Device name, data, time, GPS status, GPS latitude, GPS longitude | Every 2 seconds onboard; Every 5 minutes telemetered | 43200 per 24 hours |
| Drogue Depth | DPS Winch Pressure Sensor | Post-Survey Download | Drogue depth | Every 30 seconds | 2880 per 24 hours |
| Line Payout | DPS Winch Pressure Sensor | Post-Survey Download | Line length | Every 30 seconds | 2880 per 24 hours |

5.6 Sampling Results

Sampling results from the field demonstrations are presented below. Results are organized by technology and field event. The DPS and SeDep results are presented together for the Pearl Harbor Oscar Pier demonstration because they were used in an integrated manner.

5.6.1 DrEx Demonstration Results

The primary data collected from the DrEx systems included position data, sensor data and sample data. Position data were used to define the trajectory of the stormwater plume. Analysis of these data consisted of geospatial display and analysis. Geospatial display was performed using standard geographic information system (GIS) tools including ArcGIS, MatLab and GoogleEarth. These analyses were used to provide a visual display of the receiving water areas that are influenced by the stormwater plume. Spatial analysis tools were used to calculate statistics related to travel distance, dispersion, and area of influence. Sensor data from the DrEx included temperature and salinity from the onboard data logger. These data were examined to determine the relative fraction of stormwater in the surface plume, the change in that fraction over time, and the degree to which the DrEx systems stayed within the stormwater plume. Source and background water endpoint characteristics for temperature and salinity were used to support this analysis. Results from the chemical and toxicological analysis of the composite and passive samples were used to calculate statistics related to exposure and effects associated with the discharge plume.

Verification data for the DrEx demonstration included sub-meter resolution GPS data and plume mapping data from the survey boat using a towed or profiled CTD system. Differences between the paired samples from the drifter and verification GPS data sets were analyzed to evaluate the accuracy of the DrEx trajectory data. This analysis focused on the statistics of the root-mean-square (RMS) location differences. Plume mapping data from the towed/profiled CTD were used to produce a series of spatial maps of temperature and salinity. These maps were overlaid with the DrEx positions to qualitatively evaluate the correspondence of the trajectories with the observed location of the discharge plume. Reliability of the DrEx communications link was analyzed to determine the percent of time that the communications link is maintained during the survey period. The survivability of the units was calculated as the percent of units that successfully completed the mission, accounting for units that were lost, disabled, malfunction, etc. Analysis was also performed to compare the programmed sample volumes to the actual collected volumes. Results for each of the two DrEx field demonstration events are presented below.

5.6.1.1 Jan 5-6, 2016 Storm Event

Precipitation and Tides: The first DrEx demonstration survey was conducted during a storm event on Jan 5-6, 2016 at the mouth of Paleta Creek at NBSD. The hydrograph for the storm (Figure 51) shows that the rainfall came in two main waves with the main wave occurring between about 08:00 and 15:00 on 1/5/16, and the second smaller wave coming between about 12:00 and 14:00 on 1/6/16 (after the drifters had been retrieved). The

cumulative rainfall for the first wave was about 45 mm. Ten drifters were released into the first flush of this event at the mouth of Paleta Creek. The first flush was identified by monitoring the salinity at the mouth of the creek. Ten DrEx systems were released during the period from 13:34 to 14:11 on 1/5/16. The systems were allowed to drift for an exposure period of approximately 12 hours. The tide was flooding during the release period, and cycled from flood to ebb and back to flood during the drift period (Figure 51). Tidal range was on the order of 1 m during the event.

DrEx GPS Tracking: Trajectories for the DrEx systems are shown in Figure 52. Nine out of the ten DrEx units provided trajectory data, while one unit (109) shut down and did not record trajectory data due to a malfunction with the magnetic reed switch. The drifters followed a fairly similar path toward the southwest from the release point and along the northern side of the Mole Pier until reaching the pier head. At that point, five of the systems transited around the end of the Mole Pier to the south (along the ship channel) and into the area between the Mole Pier and Pier 10. The other four systems returned into the original area between the Mole Pier and Pier 8. The systems that transited to the south into the Mole Pier/Pier 10 area generally eddied around within the pier area with three ending up near the head of the Mole Pier, and two ending up further in adjacent to a ship that was moored on the south side of the Mole Pier. Of the systems that returned to the Mole Pier/Pier 8 area, three transited all the way back into the creek mouth area, close to the original release point, and one eddied off to the north near Pier 8 and ended up in the central portion of the outer pier area.

A number of useful characteristics can be extracted from the trajectory data including travel distance, speed, and spreading rates. These metrics provide insight into the scale, movement and dispersion of the stormwater plume. Results for travel distance and average speed are shown in Figure 53 and Figure 54, respectively. The travel distance results show that the waters associated with the first flush traveled distances ranging from about 2.3 – 3.7 km with an average distance of about 3.1 km. Given that the distance from the release point at the mouth of Paleta Creek and the pier head is about 0.9 km, this means that the drifters essentially transited about three times this distance during the 12 hour tracking period. Thus the exposure area associated with the first flush is relatively large and extends well outside the immediate area of the discharge. The average transit speed during the deployment ranged from 5.4 – 8.7 cm/s with an overall average of 7.1 cm/s. This is generally consistent with expected tidal current velocities in the area, but see also the subsequent discussion regarding the variation in speed with time. The results also indicate that drifters released during the mid-portion of the first flush were more likely to be retained in the Mole Pier/Pier 8 area, while drifters released during the beginning and later parts of the event were more likely to transit to the Mole Pier/Pier 10 area. This is in spite of the fact that the units were all released within a span of about 36 minutes. This suggests that water parcels that are initially located quite close together can become widely separated within a matter of hours following discharge. See further discussion of this below.

Results for the spreading distance and patch size are shown in Figure 55 and Figure 56, respectively. The spreading distance was estimated based on the root-mean-square distance from the drifter cluster centroid, and the patch size based on the mean-square distance, where the drifter cluster centroid is average location of all the drifters in the

cluster. Separate estimates were made for the DrEx cluster that stayed in the Mole Pier/Pier 8 area and the cluster that transited to the Mole Pier/Pier 10 area, as well as the analysis for the combination of all drifters. For the case of all drifters, the spreading and patch size growth was minimal during the early portion of the transit, and then increased fairly dramatically at about Julian Date 5.73 (where Julian Date refers to the numerical day from 1-365 of the year 2016). During the subsequent period up to about Julian Date 5.9 the group grew considerably with the mean displacement from the centroid growing from about 30 m to 300 m, and the patch size growing from less than 1000 m² to about 95000 m². After this time, the overall group size grew at a slower rate, eventually reaching a patch size of about 130000 m² at the end of the 12-hour survey period.

The spreading was also evaluated independently for clusters that separated into the Mole Pier/Pier 8 and the Mole Pier/Pier 10 areas. These clusters showed similar behavior with the clusters gradually growing in displacement and patch size up to about Julian date 5.9. After that time, the Mole Pier/Pier 8 cluster continued to grow and then stabilized toward the end of the survey, while the Mole Pier/Pier 10 cluster re-converged with the displacement and patch size shrinking. Also evident in both of the clusters are shorter periods of divergence and convergence that may to be associated with the frontal behavior described in the sensor data analysis section below.

The DrEx trajectories can also be examined with respect to the influence of tidal condition. As previously described (Figure 51), the tide was flooding during the drifter release and subsequently cycled through an additional ebb and flood cycle during the 12-hour deployment. Figure 57 shows the trajectories for individual drifters with the tidal condition overlaid on the path. The tidal overlays indicate that the drifters generally flowed out of the creek mouth area under the influence of the stormwater flow in spite of the flood tide condition. As the drifters exited the narrower channel area near the creek mouth, they slowed and circled through a clockwise eddy near the Mole Pier shoreline, then continued toward the main channel as the flood tide weakened. Most of the drifters reached the edge of the main channel at the pier head as the tide approached slack high water. At this point all of the drifters turned south along the channel, with four of the units re-entering the Mole Pier/Pier 8 area, and the other five continuing to transit south and into the Mole Pier/Pier 10 area as the tide transitioned to ebb. Interestingly, the four drifters that re-entered the Mole Pier/Pier 8 area continued to transit back into the creek mouth area in spite of the fact that the tide was ebbing, and the creek was still flowing (weakly).

Overall, the GPS tracking data from the DrEx systems provided a clear visualization of the area of the bay with connectivity to the stormwater plume, the spatial and time scale of the plume, the rate of movement of the plume, the rate of spreading of the plume, and the relationship to complex forcing from the stormwater and the tide. These are all key aspects in understanding the complex nature and extent of the stormwater exposure associated with the stormwater discharge event.

DrEx Sensor Data: Sensors mounted on the DrEx units recorded temperature and salinity continuously during the survey event. Evaluation of this data focused primarily on the salinity data because it provides a direct indicator of the presence of the stormwater plume and the degree of mixing with bay water. Results for the sensor data are described below.

Salinity time-series results for the DrEx sensors are shown in Figure 58. All ten of the drifters provided usable sensor data including 109, even though no position data were collected for the unit. The time-series results indicated that the drifters generally stayed within the plume based on the salinity levels remaining well below ambient bay levels. Values were generally low and then rose within the first hour of transport. Values then stabilized for the drifter cluster that traveled to the Mole Pier/Pier 10 area. For the drifter cluster that stayed within the Mole Pier/Pier 8 area, the salinities tended to drop again as the drifters re-entered the area of the creek mouth.

The rapid rise in salinity that generally occurred during the first hour of transit is thought to be related to the stormwater plume dynamics at the leading edge of the plume. Because the drifters were released during the first flush condition, they tended to be located near the leading edge of the plume. The combination of the buoyancy driven flow of the freshwater trying to spread out over the more saline bay water, and the shear force on the underside of the plume as it rides over the bay water results in a downwelling condition at the leading edge of the plume (Figure 59). Within the plume, freshwater moves toward this downwelling front, but when it reaches the front, it tends to recirculate back beneath the plume under the influence of the shear on the bottom of the plume. Because the drifters cannot follow the downwelling, they tend to ride out toward the leading edge of the plume and become trapped in the downwelling zone. In this zone, the salinity can drop significantly over very short spatial scales. Mixing can also be quite dramatic in this area. The drifters may move back and forth across this front resulting in some of the variations in salinity observed in the time series.

In addition, while Paleta Creek is by far the largest source of stormwater in the immediate pier areas where the drifters were located, there are numerous other small storm drains that discharge into the area. As the drifters transited under the influence of the plume and tidal currents, it is likely that they also encounter the low salinity zones associated with these other discharges. Thus they provide a unique integration of the exposure that occurs under real field conditions.

The salinity sensor data can also be combined directly with the DrEx trajectory data to provide spatial maps of the salinity zones encountered along the trajectories (Figure 60). These maps provide a visual indication of the variation in strength of the stormwater exposure over the period of the event. The salinity data can also be used to calculate the stormwater fraction along the drifter tracks as

$$SW = 1 - \frac{S}{S_o}$$

where SW is the fraction of stormwater within the plume, S is the measured salinity, and S_o is the background bay water salinity (~33.75 psu). Results for the stormwater fraction are shown in Figure 61. The results show that while the stormwater fraction often started close to 100% at the time of release, the plume was quickly diluted with bay water even

within the narrow channel area near the creek mouth such that the stormwater fraction was generally reduced to within the range of 20-40%.

In general, the sensor data from the DrEx units were very useful in evaluating the dynamics of the stormwater plume, the dilution of the plume over time, and the influence of other stormwater sources in the general vicinity.

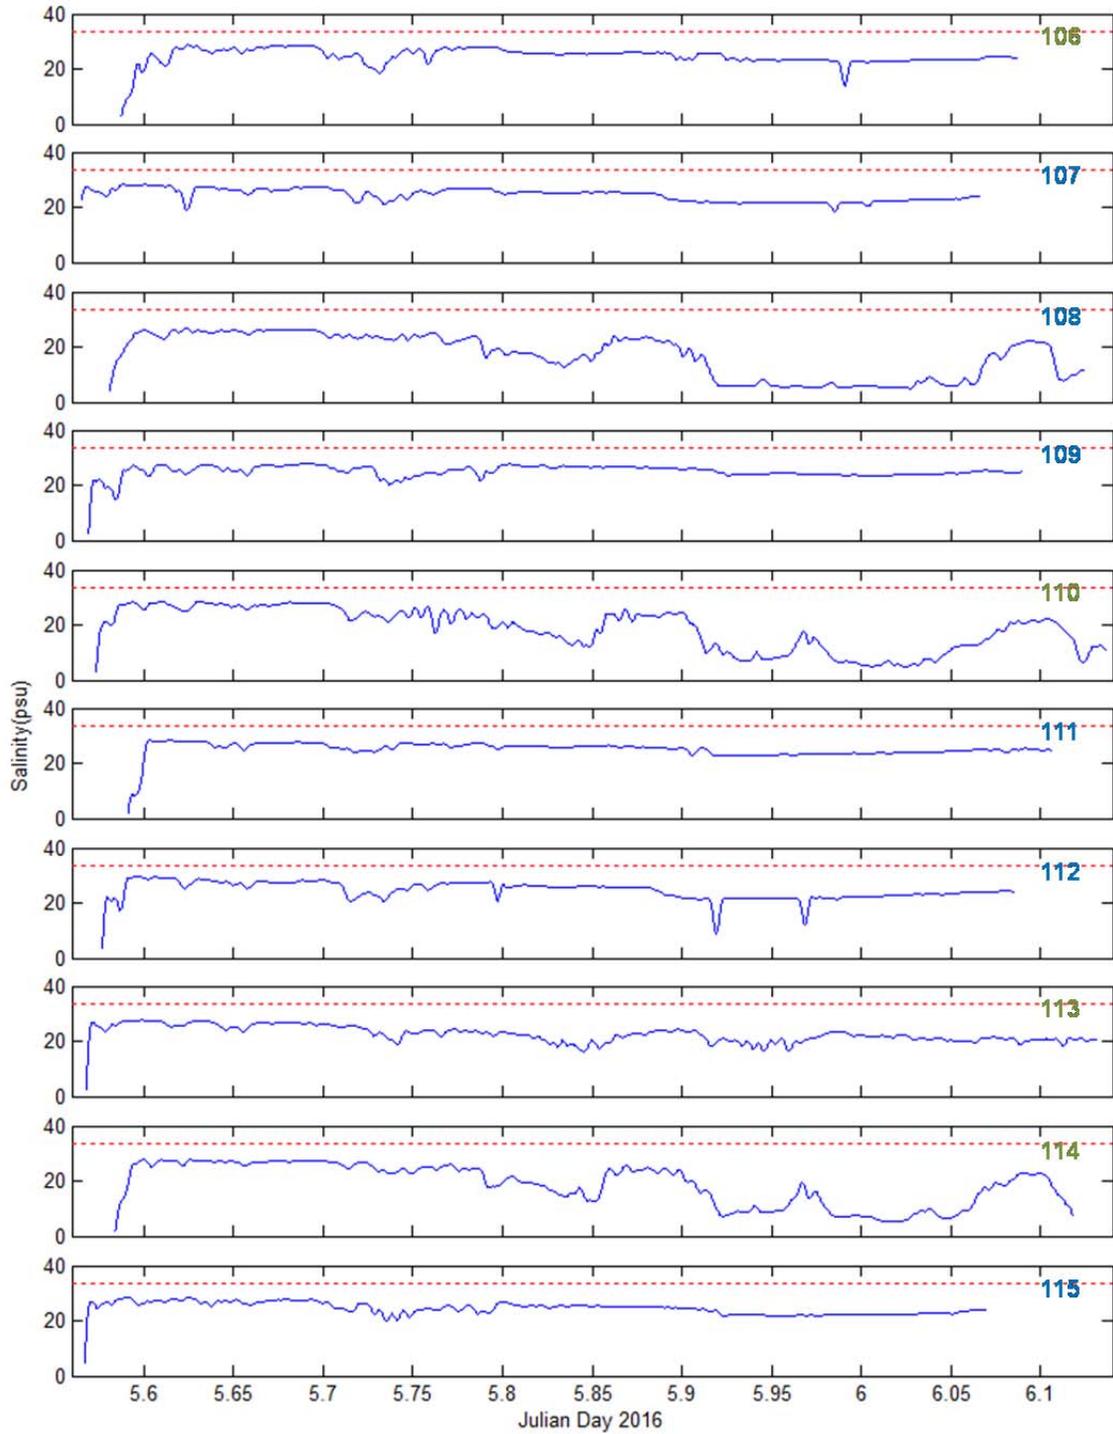

Figure 58. Time series of salinity for the ten DrEx units released during the Jan 5-6, 2016 event. Blue line is salinity and red dotted line is the background salinity level of the bay. Drifter numbers are shown in the upper right of each time series with green text indicating the Mole Pier/Pier 8 cluster, and blue indicating the Mole Pier/Pier 10 cluster.

DrEx Composite Samples: A unique aspect of the DrEx system is its ability to collect composite samples while drifting and tracking the stormwater plume. This sampling capability allows for both chemical and toxicological characterization of the exposure that occurs in the surface waters of these stormwater plumes. This exposure is much more characteristic of the exposure that would be expected for the sensitive larval stage of species such as fish and mollusks that inhabit the bay.

For the Jan 5-6,2016 storm event, composite samples were successfully collected by eight of the DrEx units (106,107,108,110,111,112,113 and 114). Faulty tube connections, bag leaks, and magnetic switch malfunctions all impacted the sampling to some degree. The sample for unit 113 was successfully collected and weighed, but subsequently the sampling bag developed a leak while the sample was in storage, and the volume was lost. Thus chemistry and toxicity results were obtained for a total of seven DrEx units. In addition, grab samples were collected at the mouth of the creek at the time of first flush when the drifters were released. An equipment blank was also collected.

Chemistry results for the samples described above are summarized in Table 16 and Figure 62 through Figure 66. Samples were analyzed for chemicals of interest for the Paleta Creek TMDL including TSS, metals (copper and zinc), PCBs, PAHs and the chlorinated pesticides Dichlorodiphenyltrichloroethane (DDT) and Chlordane. TSS concentrations ranges from a high of 276 mg/L in the discharge sample to a low of 10.7 mg/L in the DrEx-106 unit composite sample. Results for TSS show the expected high level of particulate in the discharge from Paleta Creek but significantly reduced levels in the DrEx composite samples. The reduction in particle load between the discharge and the 12-hour composite samples averaged about 94%. The average TSS concentration for the DrEx composite samples was 17.9 mg/L which is still significantly higher than typical background conditions.

Similar patterns were observed for total concentrations of metal and organic contaminants. Highest concentrations for all contaminants were observed in the first flush discharge sampler. Total copper concentrations were about 92% lower in the composite samples compared to the discharge and total zinc concentrations were reduced by about 88% on average. For Total PCBs, DDX, and Chlordane, concentrations were reduced to levels below detection limits. For Total PAHs, DrEx composite samples were about 98% lower than discharge samples. Thus overall exposure to total chemical concentrations was generally reduced by about 88-98% in the stormwater plume over a 12-hour period compared to concentrations in the first flush measured at the discharge point at the mouth of the creek.

Evaluation of the dissolved and total concentrations of metals provides some insight into the processes that influence these differences. In general, the majority of reduction in concentration for copper and zinc was related to reductions in the particulate phase (Figure 63 and Figure 64). In contrast, differences in dissolved concentrations between the discharge sample and the DrEx composite samples were minimal. This appears to reflect the fact that dissolved metal concentrations in the discharge were similar to the ambient dissolved metal concentrations in the bay, and thus dilution of the stormwater plume by ambient bay water over the 12-hour exposure had minimal influence on the dissolved metal concentrations. Thus changes in total concentrations between the

discharge and the composite plume samples appears to have been primarily driven by a combination of mixing and particle settling during the evolution of the stormwater plume. The degree of reduction associated with mixing was estimated from the average salinity sensor data for each DrEx unit and the measured salinity of the discharge sample (3.32 psu) to be about 61%. Thus particle settling would have to explain the remainder of the reduction in the range of 27-37%. So both processes appear to be important in understanding the exposure in the stormwater plume.

Toxicity was also evaluated in the discharge and DrEx composite samples. Chronic toxicity testing with purple sea urchin (*Strongylocentrotus purpuratus*) embryos was performed using standardized protocols (USEPA, 1995; Table 17). For the Jan 5-6 storm event, samples from DrEx 106 and 107 resulted in toxic responses at the highest testable concentration using student's t-test when compared to laboratory controls. The Test for Significant Toxicity (TST) provided similar results and also found the sample from DrEx 114 to be significantly lower from its respective controls.

Based on the available chemistry data, it appeared that measured levels of organic contaminants were generally too low to cause toxicity. Dissolved copper and zinc levels were also generally relatively low, but in some instances were approaching levels that could cause chronic toxicity. To evaluate this, we used a linear model to related dissolved copper and zinc relative to percent normal development for the urchin embryo. Evaluating the entire data set revealed the sample for DrEx 107 as an outlier. Results for the remaining data set showed a very strong relationship (Figure 67) with 99% of the variance explained by the model. This model has the form

$$\%ND = A + B \times [Cu_d] + C \times [Zn_d]$$

where %ND is the toxicity as percent normal development, *A*, *B* and *C* are the weighting terms for the linear model determined by best fit to the data, and $[Cu_d]$ and $[Zn_d]$ are the dissolved copper and zinc concentrations, respectively. In this model, *A* is the intercept on the toxicity axis, while *B* and *C* are weights for the copper and zinc concentrations whose inverses essentially represent empirical toxicity thresholds for these dissolved metals based on the model fit to the data. Best-fit model results give

$$\frac{1}{B} = 15.5 \frac{\mu g}{L}$$

and

$$\frac{1}{C} = 56.8 \frac{\mu g}{L}$$

These values are generally consistent with the range of observed chronic toxicity thresholds for the purple sea urchin for these dissolved metals.

Overall, the composite samples from the Jan 5-6, 2016 event provided an effective means for characterizing exposure conditions within the first flush portion of the discharge plume from both a chemical and toxicological perspective.

DrEx Passive Samplers: In addition to the composite sampling capabilities, the DrEx system can also accommodate passive samplers. For the Jan 5-6, 2016 storm event, we incorporated DGT samplers for metals, and SPME samplers for organic contaminants. The DGTs were simply attached to the drifter frame at mid depth and exposed to the stormwater plume over the 12-hour period of the event. For the SPME samplers, we enhanced the flow over the sampler by using a battery-powered pump with the SPME fibers installed in a Teflon tube in line with the pump flow.

DGT samplers were recovered from all ten DrEx units. Duplicate DGT samplers were analyzed for cadmium, copper, lead, and zinc (Table 18). Post-evaluation of the zinc results indicated that there was contamination of the DGT samples for zinc, most likely either by the acid used in the digestion, or in the DGT resin itself. Values were corrected based on bias determinations from zinc blanks run during a parallel study during the same sample batch. For this reason, the zinc results have a high degree of uncertainty. Water concentrations derived from DGT samplers are generally inferred to represent the labile fraction of the metal. For this reason, they generally have values that are a fraction of the dissolved phase concentration. Labile copper concentrations ranged from a low of 2.0 $\mu\text{g/L}$ to a high of 3.1 $\mu\text{g/L}$ (Figure 68), representing on average about 96% of the dissolved fraction. Labile zinc concentrations ranged from a low of 6.6 $\mu\text{g/L}$ to a high of 11.1 $\mu\text{g/L}$, representing on average about 74% of the dissolved fraction. The highest labile zinc concentration occurred in the sample with DrEx unit 107 which also had a very low particulate zinc fraction, and an unexplained high level of toxicity based solely on the dissolved copper and zinc levels. Cadmium, nickel and lead levels were all relatively low and uniform across the ten DrEx samples. In general, the DGT samplers were relatively easy to adapt to the DrEx units and are well suited to exposure durations that are likely to be typical for the DrEx system.

SPME samplers were recovered from all ten DrEx units. SPME samplers were analyzed for PCBs, PAHs and chlorinated pesticides. Samplers were processed and extracted at the Space and Naval Warfare Systems Center Pacific (SSC-PAC) environmental laboratory in San Diego, California. A nominal volume of 1.6 mL of hexane was added to the amber glass vial for extraction. Unfortunately, when the vials were received at the analytical laboratory, it was found that the inadvertent use of pre-split caps on the vials had resulted in either evaporation or leakage of the hexane extract. Loss of hexane volume ranged from 43% to 96%. None of the samples arrived with fibers fully submerged. This causes uncertainty with the passive sampling results for the Jan 5-6, 2015 event. Therefore, freely dissolved concentrations were calculated for demonstration purposes only.

In an attempt to correct for the sample loss due to the split caps, we evaluated the relationship between PRC congener mass and the fraction of sample loss for each PRC (Figure 69). Our assumption was that if the leakage resulted in mass loss from the sample, then the amount of mass loss would be directly proportional to the amount of sample loss because the only source of the PRC compound in the sample should be from the spiking of the SPME fibers. Analysis of the data showed that this was the case, and that the samples fell along two linear trends, one defined by the blanks, and one defined by the DrEx field samples. The results showed the same trends for all four PCB congeners that were used as PRCs. The interpretation of these two trends was that the blank samples were not exposed in the field and thus had a different relationship than the

DrEx samples that were subject to PRC loss during the 12-hour field exposure. We also found that some of the DrEx samples (107, 108, 109 and 113) fell along the low-loss blank trend rather than the field sample trend. We interpreted this to indicate that there was likely a problem with the pumping on those samples that limited the PRC loss or some factor other than sample loss that influenced the PRC levels. Using these trends, we were able to estimate the average PRC concentration for the two groups of samples as the intercepts of the regression lines shown in Figure 69. Based on these corrected values, the samples with a clear signature of high PRC loss (106, 110, 111, 112, 114, and 115) showed reasonable values for percent of steady state reached, ranging from a high of 74% for tri-chlorinated PCBs (congener 29), to a low of 58% for hexa-chlorinated PCBs (congener 154). Using these relationships, we were also able to develop correction factors for each of the samples to correct for the mass loss. These correction factors are summarized in Table 19.

Final corrected results for the SPME samples are summarized in Table 20 for summed PCB homologues and total PCBs. In general, PCB concentrations were below detection limits for most congeners. Total PCBs were generally less than 1 ng/L with the highest concentration of 0.54 ng/L in DrEx 115. PCBs were detected in at least one sample for congeners 132/153, 146, 147/149, 180, 183, and 187. However, with the exception of congener 180, these congeners were also detected at similar levels in at least one of the field blanks or trip blank, indicating that these low level detections are likely spurious and due to analytical artifacts, impurity in the PRC solution, or contamination in the sampling process.

PAHs and chlorinated pesticides were also analyzed from the SPME samples. Three PRCs were used for these compounds (all deuterated PAHs) including Acenaphthylene-d8, Benzo(a)pyrene-d12, and Pyrene-d10. The effects of sample loss on the PRCs and analytes were evaluated using the same method as described above for PCBs. The PAH PRCs showed similar trends with the blanks separated from the field-exposed samples. However, for PAHs, only field samples 107 and 113 showed low-loss response similar to the blanks (as opposed to 107, 108, 109 and 113 for PCBs). This suggests that variations in field samples 107 and 113 were likely due to pumping issues, while the variation from field response in samples 108 and 109 for PCBs was likely due to some other unidentified cause. Also, while the field-exposed PCB samples showed a clear linear response with sample loss fraction, the PRC levels in field-exposed PAH samples was flat, suggesting that the samples had already lost the majority of the PRC so there was limited influence from the sample volume loss. Using this approach, we were able to estimate the average PRC concentration for the two groups. Based on these corrected values, the samples with a clear signature of high loss (106, 108, 109, 110, 111, 112, 114 and 115) showed reasonable values for percent of steady state reached, ranging from 91-100%. However, because there was no clear relationship between sample loss fraction and PRC concentration for the field exposed samples, we were unable to develop correction factors to correct for the mass loss and thus concentrations are reported based on uncorrected masses. The only corrections made were to use the low-loss field blank and trip blank regressions to correct the blank concentrations.

Final results for the SPME samples are summarized in Table 21 for total PAHs and chlorinated pesticides. In general, only PAHs and dieldrin were detected in the DrEx

samples. PAHs and dieldren were not detected in any of the blanks. Concentrations of total PAHs ranged from below detection to a high of 158.4 ng/L in DrEx 110. The average total PAH level in the six samples with detections was 106 ng/L. This is somewhat higher than the levels detected in the composite samples, but there is a relatively high level of uncertainty with the SPME results due to the sampling and processing issues discussed previously. Concentrations of dieldren ranged from below detection to a high of 0.38 ng/L. Dieldren was not detected in the composite samples, but the detection limit was significantly higher (0.3 ng/L) and thus detections would not have been expected unless they were associated with particles. Results for total chlordane and DDX were consistent between the SPME and composite sampling results in that there were no detections in any of the samples.

Overall, while still developmental, the passive sampler results indicated that there is potential for their application on these drifting exposure systems. The DGT samplers are better suited to the application because the exposure time scale is more in line with the standard DGT method. The SPME samplers have potential, but the application is not truly passive because it requires pumping, and more work is needed to better refine the method and improve the response time.

Notes:

- 1 The concentration of PCB Homologs in each sample were calculated as the sum of the detected PCB congeners. If no congeners were detected, the maximum detection limit for the congeners within the homolog group is reported.
- 2 Total PCBs were calculated as the sum of the detected PCB homologs. If concentrations were non-detect for all homologs, total PCBs were assumed to be equal to the highest homolog detection limit.
- 3 NC results were not calculated because conditions were insufficient to reach 1% of steady state.
- 4 PCB congeners 132/153, 146, 147/149, 183, and 187 were detected in the blanks as well as field exposed samples at similar masses. Detection of these congeners is likely spurious and due to analytical artifact, impurity in the PRC solution, or contamination in the process. Results on PRC solution are pending.

Notes:

- 1 The concentration of each summation was calculated as the sum of all the compounds of that group. If no compounds were detected, the maximum detection limit for the compounds within the group is reported.
- 2 NC results were not calculated.

5.6.1.2 Feb 1, 2016 Storm Event

Precipitation and Tides: The second DrEx demonstration survey was conducted during a storm event on Feb 1, 2016 in the same area as the first survey at the mouth of Paleta Creek at NBSD. The hydrograph for the storm (Figure 70) shows that the rainfall came in a series of small waves between about 21:00 on 1/31/16 and 15:00 on 2/1/16. The cumulative rainfall for the first wave was only about 5 mm even though the prediction for the storm was for >10 mm. Ten DrEx drifters were released into the first flush of this event at the mouth of Paleta Creek. The first flush was identified by monitoring the salinity at the mouth of the creek. Ten DrEx systems were released during the period from 08:24 to 09:21 on 2/1/16. The systems were allowed to drift for an exposure period of approximately 7.5 hours with the shortest duration being about 6.7 hours and the longest duration about 8.5 hours. The deployment was cut short from the planned 12 hour exposure due to high wind and wave conditions combined with a lower than expected precipitation and flow from the creek. The tide was flooding during the release period, and cycled from flood to ebb during the drift period (Figure 70). Tidal range was on the order of 1 m during the event.

DrEx GPS Tracking: Trajectories for the DrEx systems are shown in Figure 71. All ten DrEx units provided trajectory data. The drifters released earlier in the event followed a path toward the southwest from the release point out to the end of the narrow channel that forms the creek mouth area. Subsequent DrEx units traveled shorter and shorter distances with the last few units essentially staying within a close proximity to the release area. The units released earlier in the storm reversed path once they reached the end of the channel area and transited back toward the creek mouth and the release point, ending up in the southeastern corner along at the base of the Mole Pier. The other units all stayed within the release area for the duration of the event.

As with the first event, a number of useful characteristics can be extracted from the trajectory data including travel distance, speed, and spreading rates. These metrics provide insight into the scale, movement and dispersion of the stormwater plume. Results for travel distance and average speed are shown in Figure 72 and Figure 73, respectively. The travel distance results show that the waters associated with the first flush traveled distances ranging from about 0.3 – 1.5 km with an average distance of about 0.7 km. This scale is considerably (about 4X) smaller than during the large storm event of Jan 5-6, 2016. For this smaller event, the exposure area associated with the first flush was relatively small and was limited to the area within the narrow channel at the creek mouth. The average transit speed during the deployment ranged from 1.3 – 5.9 cm/s with an overall average of 2.9 cm/s. This is also considerably smaller than the larger storm event, and appears to reflect the reduced momentum associated with the stormwater plume. The drifters show a clear pattern with drifters released earlier in the first flush having higher average speeds and larger travel distances compared to those that were released later in the event. This is consistent with the tapering off of the precipitation and discharge that occurred as the drifters were released (Figure 70). Because the tidal conditions during the two events were similar, it appears that the momentum of the storm discharge had a significant effect on the scale and speed of development of the plume.

Results for the spreading distance and patch size are shown in Figure 74 and Figure 75, respectively. The spreading distance was estimated based on the root-mean-square distance from the drifter cluster centroid, and the patch size based on the mean-square distance. Estimates were made for the DrEx cluster as the combination of all drifters. For the case of all drifters, the spreading and patch size growth was highest during the first half of the event with the mean displacement growing from about 70 m to 130 m and the patch size growing from about 5000 m² to about 16000 m². During the latter half of the event, the spreading and patch size actually reduced reaching final values of about 60 m and 4000 m², respectively. The divergence during the early part of the event appears to be related to the larger displacement of the drifters that were released earlier in the first flush which resulted in a higher degree of separation. When these drifters transited back to the release area, they essentially converged with the rest of the group that had remained in that area following release, resulting in the decreases in displacement and patch size.

The DrEx trajectories can also be examined with respect to the influence of tidal condition. As previously described (Figure 70), the tide was flooding during the drifter release and subsequently cycled through an ebb flow during the ~7-hour deployment. Figure 76 shows the trajectories for individual drifters with the tidal condition overlaid on the path. The tidal overlays indicate that the first six drifters generally flowed out of the creek mouth area under the influence of the stormwater flow in spite of the flood tide condition. The final four drifters didn't transit significantly away from the release point. The drifters that did transit out the channel all tended to reverse direction shortly after the tide turned to ebb. This behavior is counter intuitive with respect to tidal flow, which would be expected to move into the creek mouth during the flood tide, and out of the creek mouth during the ebb. However, it appears that the drifters that were released earlier were more strongly influenced by the momentum from the creek flow which out competed the tidal flow to drive the drifters out of the creek. The subsequent reversal of direction back into the creek mouth area is attributed to the high wind and wave conditions that increased during the day on Feb 1, 2016 (Figure 70), and likely had a stronger influence than the tides in this backwater area of the bay. For the drifters released later in the first flush, the momentum from the discharge had already tapered off and the drifters were already near the head of the creek mouth so there was very little tidal influence and they tended to remain in the release area. As the tide began to ebb, the wind simultaneously came up and the wind and waves then tended to overcome the tidal flow and kept these later release units from transiting out of the creek mouth with the tidal flow.

Overall, the GPS tracking data from the DrEx systems provided a clear visualization of the area of the bay with connectivity to the stormwater plume, the spatial and time scale of the plume, the rate of movement of the plume, the rate of spreading of the plume, and the relationship to complex forcing from the stormwater and the tide. These are all key aspects in understanding the complex nature and extent of the stormwater exposure associated with the stormwater discharge event. The deployment during this storm with weaker discharge but higher winds also provided a clear contrast in the spatial scales associated with different stormwater discharge events.

DrEx Sensor Data: Sensors mounted on the DrEx units recorded temperature and salinity continuously during the survey event. Evaluation of this data focused primarily on the salinity data because it provides a direct indicator of the presence of the stormwater plume and the degree of mixing with bay water. Results for the sensor data are described below.

Salinity time-series results for the DrEx sensors are shown in Figure 58. Nine of the drifters provided usable sensor data, excluding 112 that lost its sensor when the bracket broke off as the unit was slammed into floating equipment that was moored in the creek mouth. The time-series results indicated that the drifters generally stayed within the plume based on the salinity levels remaining well below ambient bay levels. Similar to the first storm event, values were generally low and then rose within the first hour of transport. Values then stabilized for several of the drifters (106, 110, 113 and 115), while others showed a secondary pulses of lower salinity water (107, 108, 109, 111 and 114). These secondary pulses appeared to be linked to follow on waves of precipitation and discharge that occurred following the release of the drifters (Figure 70).

Also, as with the first storm, the rapid rise in salinity that generally occurred during the first hour of transit is thought to be related to the stormwater plume dynamics at the leading edge of the plume. Because the drifters were released during the first flush condition, they tended to be located near the leading edge of the plume. The combination of the buoyancy driven flow of the freshwater trying to spread out over the more saline bay water, and the shear force on the underside of the plume as it rides over the bay water results in a downwelling condition at the leading edge of the plume (Figure 59). Within the plume, freshwater moves toward this downwelling front, but when it reaches the front, it tends to recirculate back beneath the plume under the influence of the shear on the bottom of the plume. Because the drifters cannot follow the downwelling, they tend to ride out toward the leading edge of the plume and become trapped in the downwelling zone. In this zone, the salinity can drop significantly over very short spatial scales. Mixing can also be quite dramatic in this area. The drifters may move back and forth across this front resulting in some of the variations in salinity observed in the time series. These effects are thought to have been less significant during the Feb 1, 2016 event due to the weaker nature of the storm.

In addition, while Paleta Creek is by far the largest source of stormwater in the immediate pier areas where the drifters were located, there are numerous other small storm drains that discharge into the area. As the drifters transited under the influence of the plume and tidal currents, it is likely that they also encounter the low salinity zones associated with these other discharges. Thus they provide a unique integration of the exposure that occurs under real field conditions.

The salinity sensor data can also be combined directly with the DrEx trajectory data to provide spatial maps of the salinity zones encountered along the trajectories (Figure 78). These maps provide a visual indication of the variation in strength of the stormwater exposure over the period of the event. The salinity data can also be used to calculate the stormwater fraction along the drifter tracks as

$$SW = 1 - \frac{S}{S_o}$$

where SW is the fraction of stormwater within the plume, S is the measured salinity, and S_o is the background bay water salinity (~ 33.75 psu). Results for the stormwater fraction are shown in Figure 79. The results show that the stormwater fraction tended to vary as a function of the distance of the DrEx unit from the creek mouth. For example, DrEx units 115, 106 and 113 that transited out toward the end of the narrow channel showed reductions in stormwater fraction down to the 20-30% range, while the units that stayed near the release area generally stayed above 40-50%. Interestingly, even though the Feb 1, 2016 event was much smaller in magnitude in terms of discharge, the exposure levels in terms of stormwater fraction were comparable or higher than the higher discharge event on Jan 5-6, 2016.

In general, the sensor data from the DrEx units were very useful in evaluating the dynamics of the stormwater plume, the dilution of the plume over time, and the influence of other stormwater sources in the general vicinity.

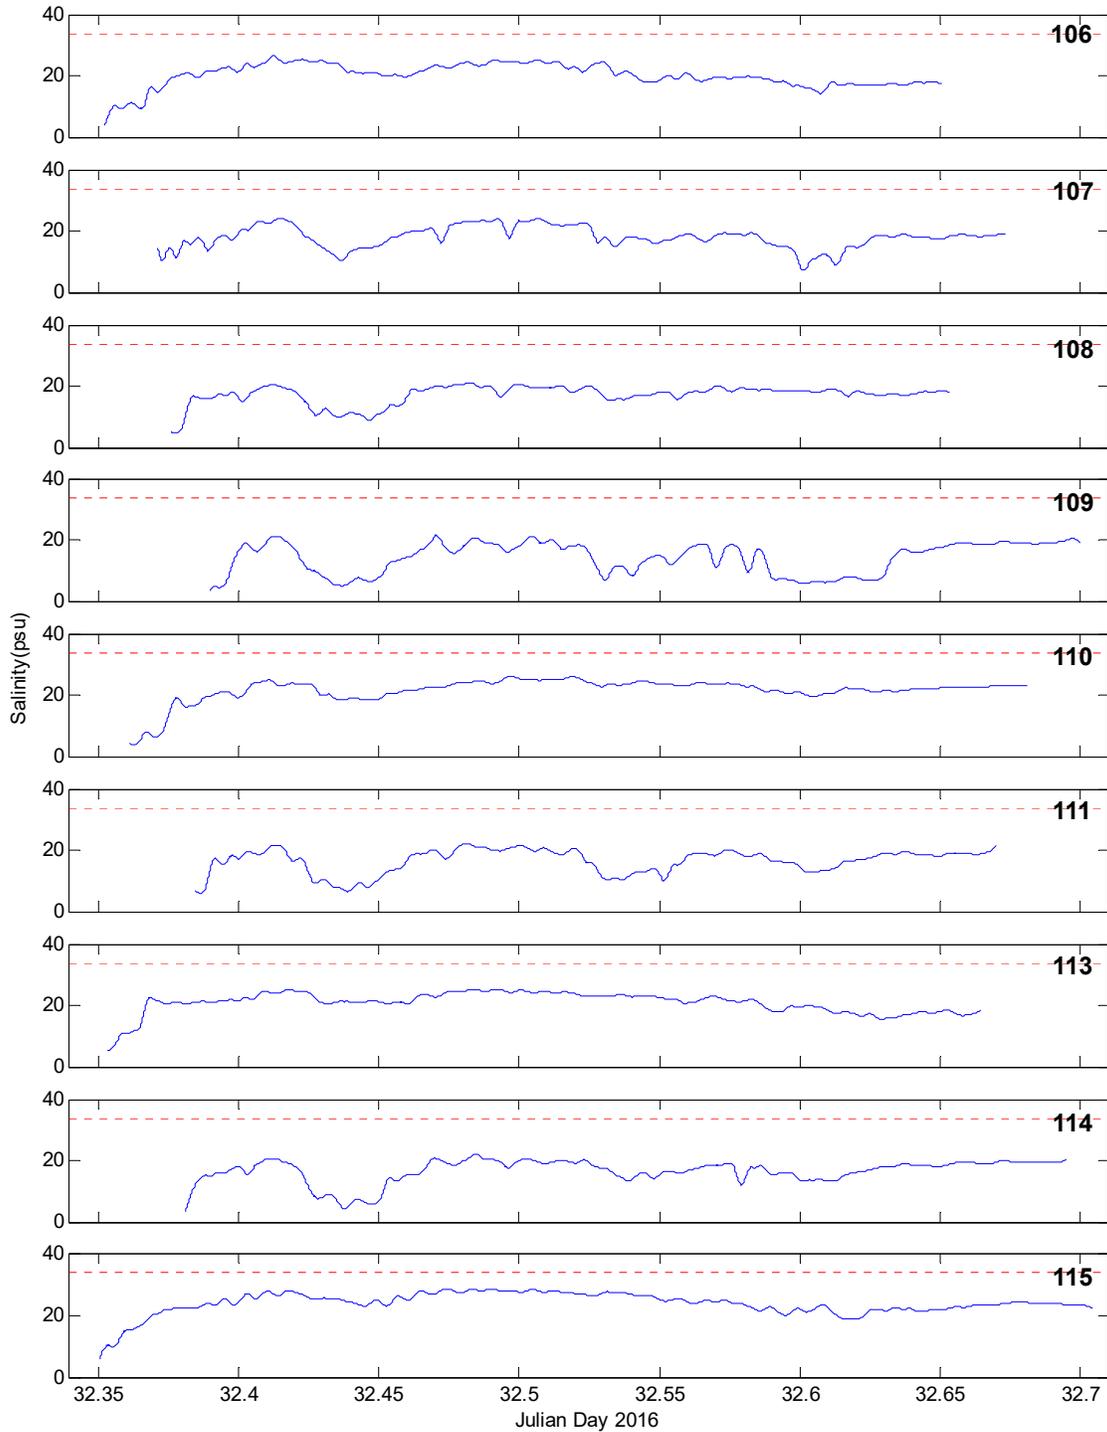

Figure 77. Time series of salinity for the ten DrEx units released during the Feb 1, 2016 event. Blue line is salinity and red dotted line is the background salinity level of the bay. Drifter numbers are shown in the upper right of each time series.

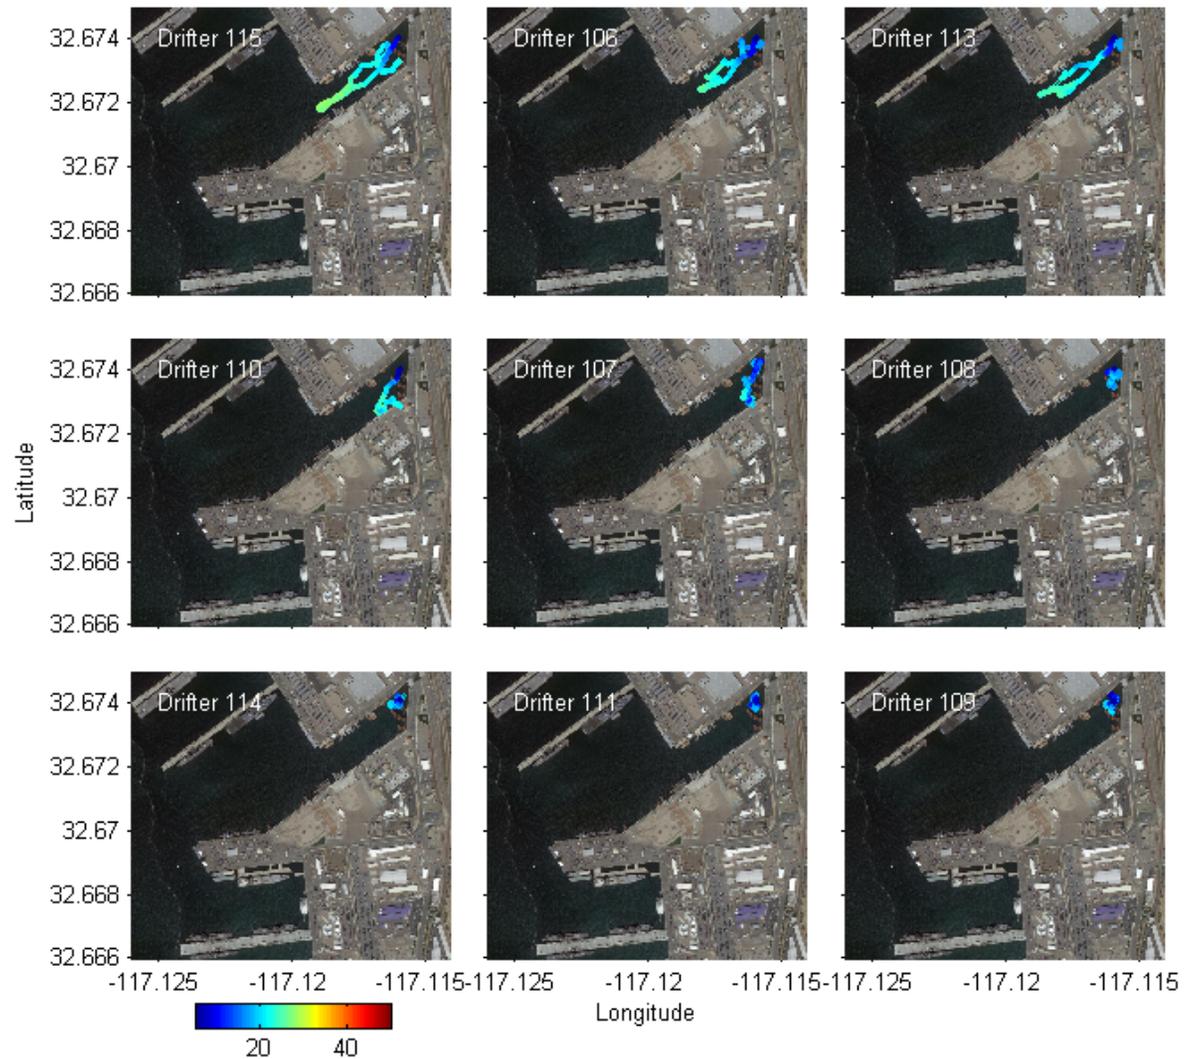

Figure 78. Individual DrEx trajectories with overlaid salinity for the Feb 1, 2016 event. Color bar indicates the salinity scale.

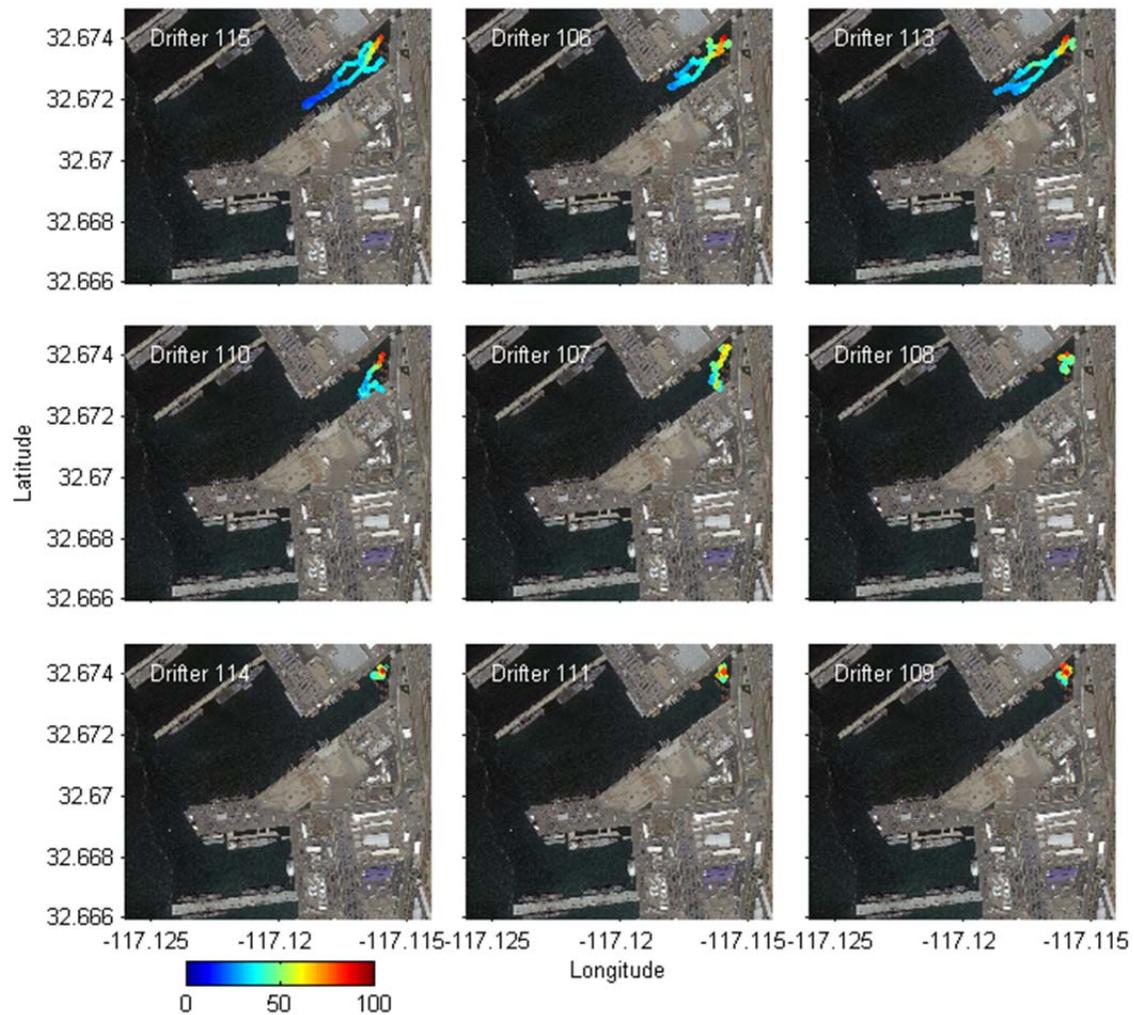

Figure 79. Individual DrEx trajectories with overlaid stormwater fraction for the Feb 1, 2016 event. Color bar indicates the percent of stormwater.

DrEx Composite Samples: A unique aspect of the DrEx system is its ability to collect composite samples while drifting and tracking the stormwater plume. This sampling capability allows for both chemical and toxicological characterization of the exposure that occurs in the surface waters of these stormwater plumes. This exposure is much more characteristic of the exposure that would be expected for the sensitive larval stage of species such as fish and mollusks that inhabit the bay.

For the Feb 1, 2016 storm event, composite samples were successfully collected by nine of the ten of the DrEx units. DrEx unit 109 had insufficient volume for analysis due to a bag leakage issue. Thus chemistry and toxicity results were obtained for a total of nine DrEx units. In addition, grab samples were collected at the mouth of the creek at the time of first flush when the drifters were released.

Chemistry results for the samples described above are summarized in Table 22 and Figure 80 through Figure 84. Samples were analyzed for chemicals of interest for the Paleta Creek TMDL including TSS, metals (copper and zinc), PCBs, PAHs and chlorinated pesticides (DDT and Chlordane). TSS concentrations ranges from a high of 71.1 mg/L in the discharge sample to a low of 10.7 mg/L in the DrEx-110 unit composite sample. Results for TSS show the expected high level of particulate in the discharge from Paleta Creek but significantly reduced levels in the DrEx composite samples. The reduction in particle load between the discharge and the 7-hour composite samples averaged about 78%. The average TSS concentration for the DrEx composite samples was 15.5 mg/L which is still significantly higher than typical background conditions. However, it should be noted that the TSS load in this discharge sample was about 4X lower than for the Jan 5-6, 2016 event. Part of this is attributed to the smaller magnitude of the storm. In addition, the timing of the discharge sampling was toward the end of the first flush just after the final drifter was released, and the flow had substantially weakened by this time which likely also contributed to the lower loading in the discharge sample from this storm event.

In contrast to the TSS, total metal and organic contaminant concentrations did not show major differences between the discharge sample and the drifter composite samples. On average, total copper and total zinc concentrations in the drifter composite samples were only 13% and 36% lower than the discharge sample, respectively. Total DDX and Chlordane were not detected in the discharge or the drifter samples. PCBs and PAHs showed some contrast with PCBs detected at low levels in the discharge, but below detection in the drifter samples, and PAHs reduced by about 41% on average in the drifter samples. Along with the sample timing considerations discussed for TSS above, it appears that the limited transport and dispersion of the plume likely contributed to the reduction in contrast between the discharge levels and plume composite samples for the smaller Feb 1, 2016 storm event. Overall exposure to total chemical concentrations was generally reduced by about 13-41% in the stormwater plume over a 7-hour period compared to concentrations in the first flush measured at the discharge point at the mouth of the creek.

A pattern that does emerge from the plume samples is that the drifters released later in the first flush tended to have higher TSS loading and total contaminant loading. This trend was consistent across all of the contaminants for which detectable levels were present.

For copper and zinc, where both the total and dissolved fractions were measured, it appeared that these trends were driven entirely by differences in the particulate fraction as opposed to the dissolved fraction which remained fairly constant across all of the composite samples. One possible explanation for this observation is that the drifters released later in the first flush had very minimal transit and dispersion scales and essentially remained trapped within the release area very close to the creek mouth. This may have exposed them to a more consistent level of particulate contamination compared to the drifters that transited further out of the creek mouth area where the particle fraction was likely to have more opportunity to settle out of the surface plume.

Toxicity was also evaluated in the discharge and DrEx composite samples. Chronic toxicity testing with purple sea urchin (*Strongylocentrotus purpuratus*) embryos was performed using standardized protocols (USEPA 1995; Table 17). For the Feb 1 storm event, using the students t-test, significant decreases from the brine control were observed for Drifters #106, 107, 108, 110, 111 and 112 (Table 23). Drifter samples #113, 114 and 115 showed no observable adverse effects compared to the brine control. Statistical analyses using the TST found adverse effects relative to the brine control in Drifter samples #106, 107, 108 and 112 (Table 23). No toxicity was observed in the remainder of the samples using the TST methodology. Interestingly, Drifter samples #110 and 111 found to be significantly decreased from the brine control using the student's t-test method were classified as Non-Toxic using the TST methodology. This is due to the a priori assigned percent difference from the control that will classify a sample as being toxic or not. In the case of samples #110 and 111, the differences from the brine control were 7.30 and 8.82 percent, respectively. The ambient sample collected at the onset of the storm did not show a significant decrease from the brine control at the highest concentration tested (Table 23).

Based on the available chemistry data, it appeared that measured levels of organic contaminants were generally too low to cause toxicity. Dissolved copper and zinc levels were also generally relatively low, but in some instances were approaching levels that could cause chronic toxicity. To evaluate this, we repeated that same linear modeling analysis to relate dissolved copper and zinc relative to percent normal development for the urchin embryo that was done for the Jan 5-6, 2016 event. Evaluating the Feb 1, 2016 data set revealed a much less robust relationship than was observed for the Jan 5-6, 2016 event (Figure 85), with only 27% of the variance explained by the model. This model has the form

$$\%ND = A + B \times [Cu_d] + C \times [Zn_d]$$

where %ND is the toxicity as percent normal development, *A*, *B* and *C* are the weighting terms for the linear model determined by best fit to the data, and $[Cu_d]$ and $[Zn_d]$ are the dissolved copper and zinc concentrations, respectively. In this model, *A* is the intercept on the toxicity axis, while *B* and *C* are weights for the copper and zinc concentrations whose inverses essentially represent empirical toxicity thresholds for these dissolved metals based on the model fit to the data. Best-fit model results give

$$\frac{1}{B} = 2.3 \frac{\mu g}{L}$$

and

$$\frac{1}{C} = 294 \frac{\mu g}{L}$$

These values are generally less consistent with the range of observed chronic toxicity thresholds for the purple sea urchin for these dissolved metals, with the copper level ($1/B$) being lower than expected, and the zinc level ($1/C$) being higher than expected. Of the chemicals measured in the composite and discharge samples for the Feb 1 event, no specific contaminant or combination of contaminants appeared to give a good explanation of the toxicity results. This suggests that, as with the DrEx 107 sample during the Jan 5-6 event, there may be another unmeasured chemical that is responsible for the observed toxicity. Another potential consideration is that there were significant differences in the DOC concentrations of the discharge samples for the two events (based on data from the leveraged project ER-2428), with the Jan 5-6 event having an average DOC concentration in the discharge of 5.6 mg/L and the Feb 1 event having an average concentration of 19.2 mg/L. Because of the potential complexation effects associated with divalent metals and DOC, these differences may have also influenced the observed differences in toxicity during the two events.

Overall, the composite samples from the Feb 1, 2016 event provided an effective means for characterizing exposure conditions within the first flush portion of the discharge plume from both a chemical and toxicological perspective.

Values in bold indicate a statistically significant decrease compared to the brine control as determined with the student's one tailed t-test.

Level of statistical significance: a - <0.05, b - <0.01, c - ≤0.001.

are as follows: Ambient (83.1%), 106 (84.0%), 107 (78.2%), 108 (78.6%), 109 (74.8%), 110 (82.6%), 111 (76.3%), 112 (84.10%), 113 (84.3%), 114 (77.2%), 115 (87.0%)

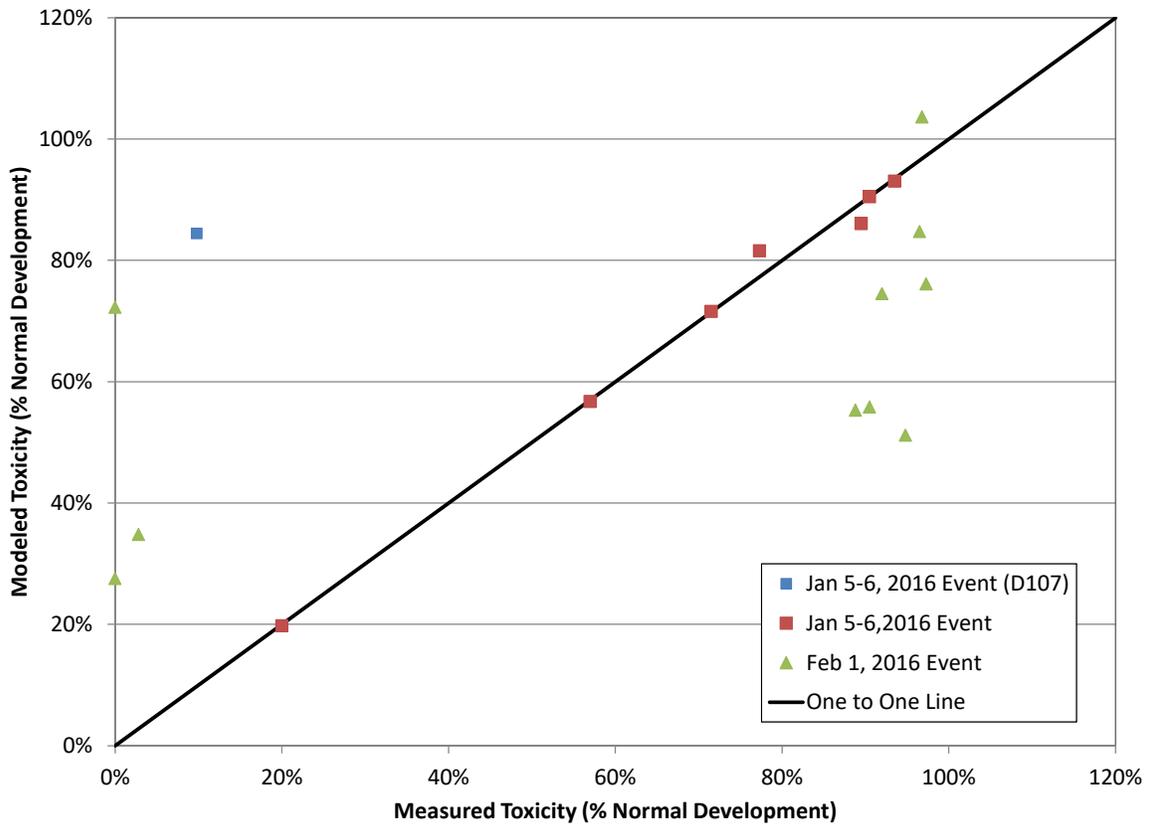

Figure 85. Modeled vs. measured toxicity based on the linear model for dissolved copper and zinc described in the text (both storm events shown).

DrEx Passive Samplers: In addition to the composite sampling capabilities, the DrEx system can also accommodate passive samplers. For the Feb 1, 2016 storm event, we incorporated DGT samplers for metals, and SPME samplers for organic contaminants. The DGTs were simply attached to the drifter frame at mid depth and exposed to the stormwater plume over the 12-hour period of the event. For the SPME samplers, we enhanced the flow over the sampler by using a battery-powered pump with the SPME fibers installed in a Teflon tube in line with the pump flow.

DGT samplers were recovered from all ten DrEx units. Duplicate DGT samplers were analyzed for cadmium, copper, lead, and zinc (Table 24). Post-evaluation of the zinc results indicated that there was contamination of the DGT samples for zinc, most likely either by the acid used in the digestion, or in the DGT resin itself. Values were corrected based on bias determinations from zinc blanks run during a parallel study during the same sample batch. For this reason, the zinc results have a high degree of uncertainty. Water concentrations derived from DGT samplers are generally inferred to represent the labile fraction of the metal. For this reason, they generally have values that are a fraction of the dissolved phase concentration. Labile copper concentrations ranged from a low of 1.2 µg/L to a high of 2.9 µg/L (Figure 86), representing on average about 54% of the dissolved fraction. Labile zinc concentrations ranged from a low of 10.8 µg/L to a high of 17.2 µg/L, representing on average about 87% of the dissolved fraction. The reduction in the labile copper fraction is consistent with the observation of significantly higher DOC in the discharge water. However there was no clear relationship between labile copper and zinc concentrations and the observed toxicity in the samples. Cadmium, nickel and lead levels were all relatively low and uniform across the ten DrEx samples. In general, the DGT samplers were relatively easy to adapt to the DrEx units and are well suited to exposure durations that are likely to be typical for the DrEx system.

SPME samplers were recovered from all ten DrEx units. SPME samplers were analyzed for PCBs, PAHs and chlorinated pesticides. Samples from the Feb 1, 2016 storm event did not suffer from the leakage issues associated with samples from the first storm event. However, the short exposure time (~7 hours) associated with the deployment, and some potential malfunctions of the circulation pumps impacted the utility of the data. The concentration of PRC PCBs of the blank average was greater than field exposed samples except samples D113 and D114, indicating either these pumps were not functioning or the pumps did not increase the elimination rate of PRCs from the Polydimethylsiloxane (PDMS) for these DrEx units. Due to inclement weather and safety concerns, the pumps were not checked at the end of this sampling event to ensure each was functioning properly; therefore, it was not possible to determine which was the case. For PCB-69, sample D108 also had concentrations greater the average of the blanks. For PCB-104 and 154, 6 to 7 of the 10 samples did not have concentrations greater than the average of the blanks, indicating the penta- and hexachlorinated biphenyls were less affected by the pump than the tri- and tetrachlorinated biphenyls. The correction factors could not be calculated for samples D108, D113, and D114 since sufficient percent to steady state was not achieved for more than one PCB PRC. For the other 7 samples, an average of 38%, 15%, 6%, and 0.5% to steady state was reached for PCB-29, 69, 104 and 154, respectively (with coefficient of variation $CV \leq 20\%$). This supports the notion that the more chlorinated the biphenyl, the less affected the elimination rate of the PRC from the

PDMS by pumping of water over the fiber. Also, it should be noted, the duration of deployment was approximately 7 hours. If the deployment time had been closer to the scoped goal of the 12 to 24 hours, each PCB PRC was likely to have reached considerably closer to steady state.

Final corrected results for the SPME samples are summarized in Table 25 for summed PCB homologues and total PCBs. In general, PCB concentrations were below detection limits for most congeners. PCBs were not detected for samples D106, D109, D111, D112, and D115. Hexa- and heptachlorinated biphenyls were detected in samples D107 and D109 with total PCB concentrations of 0.16 and 0.22 ng/L, respectively. However, these detections were potentially spurious and due to analytical artifact, impurity in the PRC solution, or contamination in the process.

PAHs and chlorinated pesticides were also analyzed from the SPME samples. Acenaphthene, anthracene, benzo (a) anthracene, chrysene, fluoranthene, fluorene, phenanthrene, pyrene, alpha-chlordane, dieldrin, and gamma-Chlordane were detected in one or more samples above reporting limits. Although the concentrations of deuterated PAHs in the blanks were largely variable (CV 40% to 101%), the average was used to calculate the correction factors. Overall, the regression models for each sample had strong correlation ($r^2 > 0.8$), with the exception of samples D111 and D114, due to the high concentration of pyrene-d10 in these samples compared to the other field exposed samples. Sample D113 had concentrations of pyrene-d10 greater than the average of the blanks. This may indicate the elimination rates of pyrene-d10 was not affected by the flow of water over the PDMS coating. Acenaphthylene-d8 and benzo(a)pyrene-d12 reached an average of 98% and 89% steady state, respectively, with little variability among the field exposed samples (standard deviation 1% to 7%, respectively). Though, pyrene-d10, reached an average of 77% to steady state with 47% standard deviations. However, it would be unexpected that pyrene-d10 would less readily eliminate from PDMS compared to benzo(a)pyrene based on partitioning coefficients. It may also indicate samples D111, D113, and D114 were either less affected by the pumped water or the pump was not functioning.

Final results for the SPME samples are summarized in Table 26 for total PAHs and chlorinated pesticides. In general, PAHs, chlordane and dieldrin were detected in the DrEx samples. PAHs, chlordane and dieldren were not detected in any of the blanks. Concentrations of total PAHs ranged from a low of 28.4 ng/L in DrEx 109 to a high of 2510 ng/L in DrEx 114. The average total PAH level in the ten samples with detections was 595 ng/L. This is considerably higher than the levels detected in the composite samples. Concentrations of total chlordane ranged from below detection to a high of 0.089 ng/L. Chlordane was not detected in the composite samples, but the detection limit was significantly higher (0.3 ng/L) and thus detections would not have been expected unless they were associated with particles. Concentrations of dieldren ranged from below detection to a high of 0.33 ng/L, similar to the levels observed in the Jan 5-6 event. As with chlordane, dieldren was not detected in the composite samples, but the detection limit was significantly higher (0.3 ng/L) and thus detections would not have been expected unless they were associated with particles. Results for total DDX were consistent between the SPME and composite sampling results in that there were no detections in any of the samples.

Overall, while still developmental, the passive sampler results indicated that there is potential for their application on these drifting exposure systems. The DGT samplers are better suited to the application because the exposure time scale is more in line with the standard DGT method. The SPME samplers have potential, but the application is not truly passive because it requires pumping, and more work is needed to better refine the method and improve the response time.

Table 24. DGT results for the Feb 1, 2016 event. Units are in µg/l.

Notes:

- 1 The concentration of PCB Homologs in each sample were calculated as the sum of the detected PCB congeners (Table 7). If no congeners were detected, the maximum detection limit for the congeners within the homolog group is reported.
- 2 Total PCBs were calculated as the sum of the detected PCB homologs. If concentrations were non-detect for all homologs, total PCBs were assumed to be equal to the highest homolog detection limit.
- 3 NC results were not calculated because conditions were insufficient to reach 1% of steady state, as described in Table 6.
- 4 Concentrations of PCB congeners 132/153, 146, 147/149, 183, and 187 may have been detected erroneously and were not included in these calculations (Table 3).

Notes:

- 1 The concentration of each summation was calculated as the sum of all the compounds of that group. If no compounds were detected, the maximum detection limit for the compounds within the group is reported.

5.6.2 DPS and SeDep Demonstration Results

The DPS/SeDep demonstration included two events. The first event was conducted at the Oscar Pier site in Pearl Harbor during the period March 12 – April 26, 2016 and included application of both systems. The second event was conducted at the Waiiau Generating Station site in Pearl Harbor and focused only on the DPS technology.

The primary data from the DPS deployments included the three-dimensional DPS trajectories, the bottom-detection locations, and onboard temperature and salinity. Position data from the surface float, and depth data from the drogue winch were combined to construct the three-dimensional trajectories. Geospatial display was performed using standard GIS tools including ArcGIS, MatLab and GoogleEarth. Bottom-detection locations were compiled from all of the drifter releases to develop an overall map of the deposition footprint linked to the outfall discharge location. This footprint was calculated using geostatistical mapping techniques to construct a footprint map for subsequent deployment of SeDep systems. The temperature and salinity data recorded were used to characterize background conditions of stratification in the discharge area in the absence of stormwater releases. These data were analyzed to compare surface and deeper water conditions.

Verification data for the DPS demonstration included sub-meter resolution GPS data and water depths collected at DPS locations over the course of the survey. Differences between the paired samples from the drifter and verification GPS data sets were analyzed to evaluate the accuracy of the DPS trajectory data. This analysis focused on the statistics of the RMS location differences. Water depth measurements at the drifter locations were analyzed together with the DPS drogue depth and bottom detection data to verify that the DPS bottom detection algorithm was working properly. Reliability of the communications link was analyzed to determine the percent of time that the communications link was maintained during the survey period. The survivability of the units was calculated as the percent of units that successfully complete the mission, accounting for units that were lost, disabled, malfunctioned, etc. Depth measurements and line payout were analyzed to evaluate how closely these measures track and to determine the potential horizontal offset between the surface float and the drogue. These estimates were made using a standard catenary calculation formula.

Primary data from the SeDep system included time series of sediment mass, sediment trap samples, and surface sediment samples from above the deposition sensor at the end of the deployment period. Time series data from the deposition sensor were averaged to one-hour intervals and plotted to visualize the time trend in deposition at each station. Deposition rates were examined for the overall deployment, and for events and quiescent periods during the deployment. Quiescent periods were also be analyzed to assess the in situ variability associated with the measurements. Sediment trap sample results were evaluated in the context of the time-series observations from the deposition sensors. Deposition mass in the traps was compared to the time-integrated results from the sensors. Chemistry results from the traps and surface sediment samples were used to estimate mass loading to the sediment bed via ongoing deposition.

Verification data for the SeDep demonstration included deposition detection sensitivity, measurement reliability, system survivability, and ease of use. Detection sensitivity was analyzed from field measurements based on the variability measured during quiescent periods of the deployment when no storm events, ship movements or other significant sediment transport processes were active. Evaluation of the pressure sensor response was also analyzed based on the placement of calibration mats (rubber or vinyl sheeting) on top of the sensors at the end of the deployment to check the response to a known loading. Survivability in the field was analyzed based on successful mission completion, without major system failures or lost units during field deployments. Ease of use data were summarized based on diver interviews following the deployment and retrieval phases of the demonstration.

5.6.2.1 March 12-13, 2016 DPS Event – Oscar Pier

Tides and Winds: In the absence of strong freshwater discharges, the primary influences on the circulation in Pearl Harbor are tides and winds. The DPS survey at Oscar Pier was conducted during the period from March 12-13, 2016. Tide and wind conditions for the deployment period are shown in Figure 87 relative to the DPS release and tracking period. The tracking took place over a complete diurnal tide cycle with a tidal range of about 0.5 m which is typical for Pearl Harbor. Wind conditions were also typical trade winds for the area with wind speeds ranging from about 10 mph during the night to about 20 mph during the day and generally blowing from the ENE direction. Release times for the DPS units started during a period of ebb flow, and continued through successive flood and ebb periods. There was no precipitation during the event.

DPS Tracking: During the Mar 12-13, 2016 event, a total of 17 DPS releases from the Oscar Pier area were successfully tracked to bottom contact. Three-dimensional trajectories for the DrEx systems are shown in Figure 88 – Figure 93. The trajectories showed a strong tidal dependence. During slack high water and early ebb tide conditions, DPS units generally stayed close to the shoreline and traveled southward toward the mouth of the harbor, often looping back and making bottom contact near the release point. During the latter ebb and slack low water conditions, DPS units tended to transit along the shoreline to the north and further into the harbor along the main channel. During the late flood condition, DPS unit often traveled out into the channel away from the shoreline, and then travel either north or south along the channel. The tidal influence on the DPS units led to strong spreading and dispersion for units released over the tidal cycle and a correspondingly large deposition footprint that was strongly strained to the north and south along the channel and the Oscar Pier shoreline area.

A number of useful characteristics can be extracted from the DPS trajectory data including travel distance and speed. These metrics provide insight into the scale and movement associated with the DPS trajectories. Results for travel distance and average speed are shown in Figure 96 and Figure 97, respectively. The travel distance results show that particles released from the Oscar Pier outfall traveled distances ranging from about 0.3 – 1.9 km with an average distance of about 1.0 km. The travel distance follows a trend that roughly corresponds with the different tidal conditions, with longer trajectories generally occurring for DPS units released during the late ebb and slack low water tide conditions.

The average transit speed during the deployment ranged from 2.1 – 8.3 cm/s with an overall average of 4.8 cm/s. These speeds are consistent with the relatively low current speeds in Pearl Harbor associated with limited tidal range. As with the travel distance, the transit speed also showed a correspondence with tide condition at the time of release for the DPS unit with higher speeds generally associated with DPS units released during the late ebb and slack low water tide conditions.

Settling Rate and Bottom Contact: The DPS units were programmed to simulate silt sized particle transport with an effective settling rate of 34 mm/min. Results showed that all of the DPS units followed this rate closely. Vertical profiles of the DPS depth versus time and the bottom contact depth are shown in Figure 98. The profiles show the uniform settling rate for all DPS units. DPS 9-2 showed a minor interruption at about midway through its transit. The cause is not known. Bottom contact depths ranged from about 6.8 m for DPS 1-1, to a high of 16.9 m for DPS 9-1, with an average of 11.8 m. These results suggest that the DPS units can function effectively over the expected range of depths for harbor environments. Because the settling rates were uniform, bottom contact times varied as a function of the contact depth. Settling times varied from a low of 3.3 hours for DPS 1-1, to a high of 8.3 hours for DPS 9-1, with an average of 5.8 hours.

The spatial distribution and footprint of bottom contacts are shown in Figure 94 and Figure 95. Two qualitative footprint areas were defined including the footprint that encompassed only the bottom contact locations, and a broader footprint that encompassed the trajectories and the bottom contacts. The first footprint is descriptive of the likely deposition area for silt-sized particles released from the outfall near Oscar Pier. The second footprint is representative of silt and large (faster settling) size particles based on the assumption that these particles would settle somewhere along the trajectory leading to the bottom contact location for silt.

The distribution was separated roughly into three groups including a group that stayed relatively close to the outfall (1-1, 1-2, 3-1, 4-3, 5-3 and 9-2), a group that was transported south toward the harbor entrance (9-1 and 10-1), and a group that was transported north further into the harbor (1-3, 4-1, 4-2, 5-1, 5-2, 6-1, 7-1, 7-2 and 8-1). While not supported by statistical replication, these results suggest that silt-sized particles discharged from the outfall near Oscar Pier are most likely to either settle near the outfall or be swept further into the harbor. By percentage, 35% settled near the outfall, 53% were transported and settled further into the harbor, and 12% were transported and settled further out of the harbor.

The overall spatial scale and area of the footprint were estimated based on the root-mean-square distance from the bottom contact cluster centroid, and the mean-square distance from the bottom contact cluster centroid, respectively. The length scale of the footprint based on this method was about 2.5 km, and the area was about 6.4 km². These spatial scales are relatively large and indicate that for silt particles, the footprint associated with a given outfall discharge is likely to interact with numerous other nearby outfalls. Also the results suggest that near field monitoring will pick up a portion of the discharge, but the particles associated with the discharge do not only influence the area immediately adjacent to the outfall.

Overall, the GPS tracking and bottom contact data collected using the DPS systems provided a clear visualization of the area of the harbor with connectivity to the outfall, the depth, spatial and time scales of the transport area, and the spatial location and size characteristics of the deposition footprint. These are all key aspects in understanding the complex nature and extent of the particle transport associated with discharge from a given outfall location.

DPS Sensor Data: Sensors mounted on the DPS units recorded temperature and salinity continuously during the Mar 12-13, 2016 survey event. The primary purpose of the sensor measurements was to document conditions during the deployments and demonstrate that the system can accommodate sensors of this type. The temperature and salinity data would be more relevant during an actual storm event. In addition, sensors such as transmissometers or optical backscatter sensors would also be useful during storm event deployments. For the non-storm deployments that were conducted here, the sensors primarily provide background information on site conditions. Results for the sensor data are described below.

Salinity and temperature data for the DPS sensors are shown in Figure 99 and Figure 100, respectively. Of the 17 tracking events, sensor data were successfully collected during 13. DPS units 2 and 9 did not have a sensor on board, so the deployments with those systems did not report sensor data. Data downloading issues with the data loggers on the sensors accounted for the other missing data. In general, the salinity data were relatively uniform throughout the survey event as expected for a non-storm condition. Several of the deployments showed higher salinity at depth, especially for the systems that made bottom contact in deeper water. There also appeared to be some tidal variation with slightly lower salinity conditions during the low water periods compared to high water periods. Temperature data were also relatively uniform through the survey event. Slightly warmer water prevailed just after low water conditions. Vertical temperature variations were minimal. In general, the results illustrate that the DPS system can act as a platform for sensors to track background or storm event conditions during the trajectories of the drifters.

5.6.2.2 March 15 – April 26, 2016 SeDep Event – Oscar Pier

Tides, Winds and Precipitation: Environmental conditions including tides, winds and precipitation have the potential to influence the rates and patterns of particle deposition at the Oscar Pier site. Tide and wind conditions during the survey period are shown in Figure 102. Tidal variations followed typical semi-diurnal and spring-neap patterns of variability. Tidal range varied from a low of about 0.4 m during neap tides, to a high of about 0.8 m during spring tides. Winds were generally from the northeast consistent with trade wind patterns for the area, but varied to other directions during some portions of the event. Wind speed varied on a daily basis, with stronger winds during the day and weaker at night. Wind speed was generally in the range of 5-20 mph but sustained periods of lower wind speeds also occurred, and these generally corresponded to periods of inconsistent trade winds or storms.

The goal for the SeDep deployment was to span sufficient time to capture multiple storm events discharging from the outfall near Oscar Pier. The precipitation record shows that two moderate storm events and several smaller events took place during the deployment period, totaling about 13 mm (Figure 103). This was more limited than would have been ideal, but provided some level of discharge to evaluate stormwater related deposition in the area. The primary events occurred on Mar 25, 2016 (Julian day 84; approximately 6.6 mm) and Apr 17, 2016 (Julian day 107; approximately 3.3 mm). The drainage area for the outfall is about 506000 m² (125 acres) and extends inland about 1500 m. The land cover in the area is primarily impermeable and the land use is primarily industrial. Although the discharge from the outfall is not monitored, assuming an impermeable surface over the entire area, the discharge for the two storm events would have been on the order of 3340 m³ and 1670 m³, respectively. For the entire period, the rainfall total of 12.7 mm would have resulted in a total discharge of about 6430 m³. Given typical stormwater particulate concentrations on the order of about 100 mg/L, this would translate to a total particulate load of about 643 kg discharged from the outfall over the monitoring period.

SeDep Sensor Data: Based on the DPS deposition footprint results from the Mar 12-13, 2016 event, ten SeDep units were deployed in Pearl Harbor for the period March 15 – April 26, 2016. The deployments were focused in the nearfield area of the footprint with an additional unit deployed further into the harbor and further out toward the entrance to characterize the far field areas of the footprint (Figure 101). Deposition data were collected continuously over the 42 day period of the deployment (Table 27). The first hour of data was removed to eliminate any transients associated with the installation, and the data were averaged to hourly readings.

Results for the SeDep deposition sensor data are shown in Figure 103. The SeDep results reflect direct measurements of cumulative deposition for in-water mass of sediment as calibrated against known weights placed on the pressure plates. These direct measurements were converted to dry sediment mass assuming a dry sediment density of 2.65 g/cm³. The results indicated cumulative deposition ranging from a low of about 69 g at SeDep1 to a high of about 323 g at SeDep9. In general, SeDep units placed close to the outfall and to the south of the outfall showed lower deposition, while systems placed to the north of the outfall showed higher deposition. The deposition sensors placed closer to

the outfall showed temporal patterns that appeared to be more closely correlated to stormwater discharge events. While all of the stations showed net deposition over the deployment period, some stations showed periods of erosion as well. This seemed to be more prevalent at the stations to the north of the outfall. Three of the SeDep units (3, 7 and 10) failed to work for the entire duration of the deployment due to an adhesive failure on the pressure plate that caused a loss in the pressure integrity of the system.

Cumulative deposition measurements from the SeDep were also used to calculate deposition rates based on the total deposition, the deployment duration, and the area of the deposition pressure plate. These deposition rates ranged from a low of 0.77 g/cm²/y at SeDep1 to a high of 3.61 g/cm²/y at SeDep9. These rates are generally consistent with rates measured in the harbor during the remedial investigation (US Navy, 2015).

The results seem to indicate that the deposition signals closer and to the south of the outfall are indicative of potential inputs from stormwater, while the deposition signals at stations to the north of the outfall are dominated by processes that are not strongly or directly linked to stormwater. Overall, the SeDep sensor systems provided a unique temporal quantification of cumulative sediment deposition under conditions that are representative of DoD harbors subject to stormwater and other sediment transport processes.

SeDep Sediment Trap Mass: As part of the integrated SeDep system, each station (Figure 101) included a sediment trap for the quantification of total deposited mass, and to determine the chemical characteristics of the depositing particles. Particles collected in the sediment traps over the 42 day deployment were separated from the water phase, weighed to determine wet weight, and sub-sampled for moisture content and chemistry analyses. Based on the wet weights and the moisture content measurements, the total deposited mass and deposition rate at each station were determined (Table 28). The results show that total deposited mass ranged from a low of about 17.2 g at station SeDep1 to a high of 78.2 g at station SeDep9.

Cumulative deposition measurements from the sediment traps were also used to calculate deposition rates based on the total deposition, the deployment duration, and the area of the sediment trap. These deposition rates ranged from a low of 0.82 g/cm²/y at SeDep1 to a high of 3.73 g/cm²/y at SeDep9. These rates are generally consistent with rates measured by the SeDep sensors (Figure 104; R² = 0.93), as well as previously measured rates in the harbor (US Navy, 2015). The sediment trap rates were biased somewhat higher than the SeDep measurements (Slope = 0.91), potentially reflecting differences associated with the two methods. It was expected that the traps would collect any material depositing at the location with minimal effects of erosion or resuspension, while the SeDep sensors would be subject to both deposition and erosion. Both measurements showed similar overall spatial patterns, with higher deposition rates to the north and offshore of the outfall, and lower deposition rates near the outfall and to the south. Station SeDep3 showed the largest difference between the sediment traps and the deposition sensors.

Overall the sediment traps that were collocated with the SeDep sensors provided an effective means of collecting deposited sediments, and the deposition rates were consistent with expectations regarding the typical rates in Pearl Harbor.

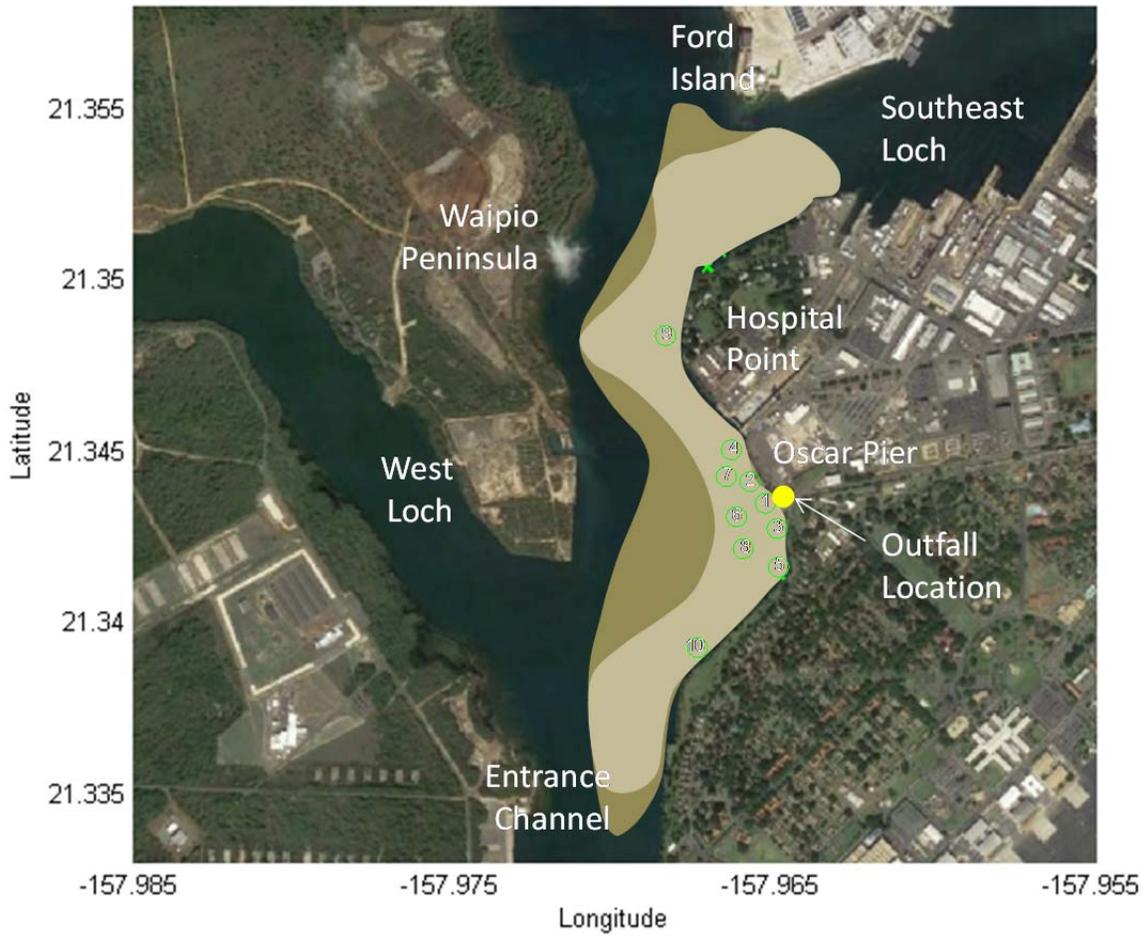

Figure 101. Location map for the SeDep systems in Pearl Harbor during the March 15 – April 26, 2016 event.

Table 27. Deployment locations, times, duration, deposited mass and deposition rates for the SeDep sensors during the Mar 15 – Apr 26, 2016 event.

| SeDep Station | Longitude (deg W NAD83) | Latitude (deg W NAD83) | Start | End | Deployment Duration (days) | Final In-Water Weight (g) | Final Dry Weight (g) | Deposition Rate (g/cm ² /y) |

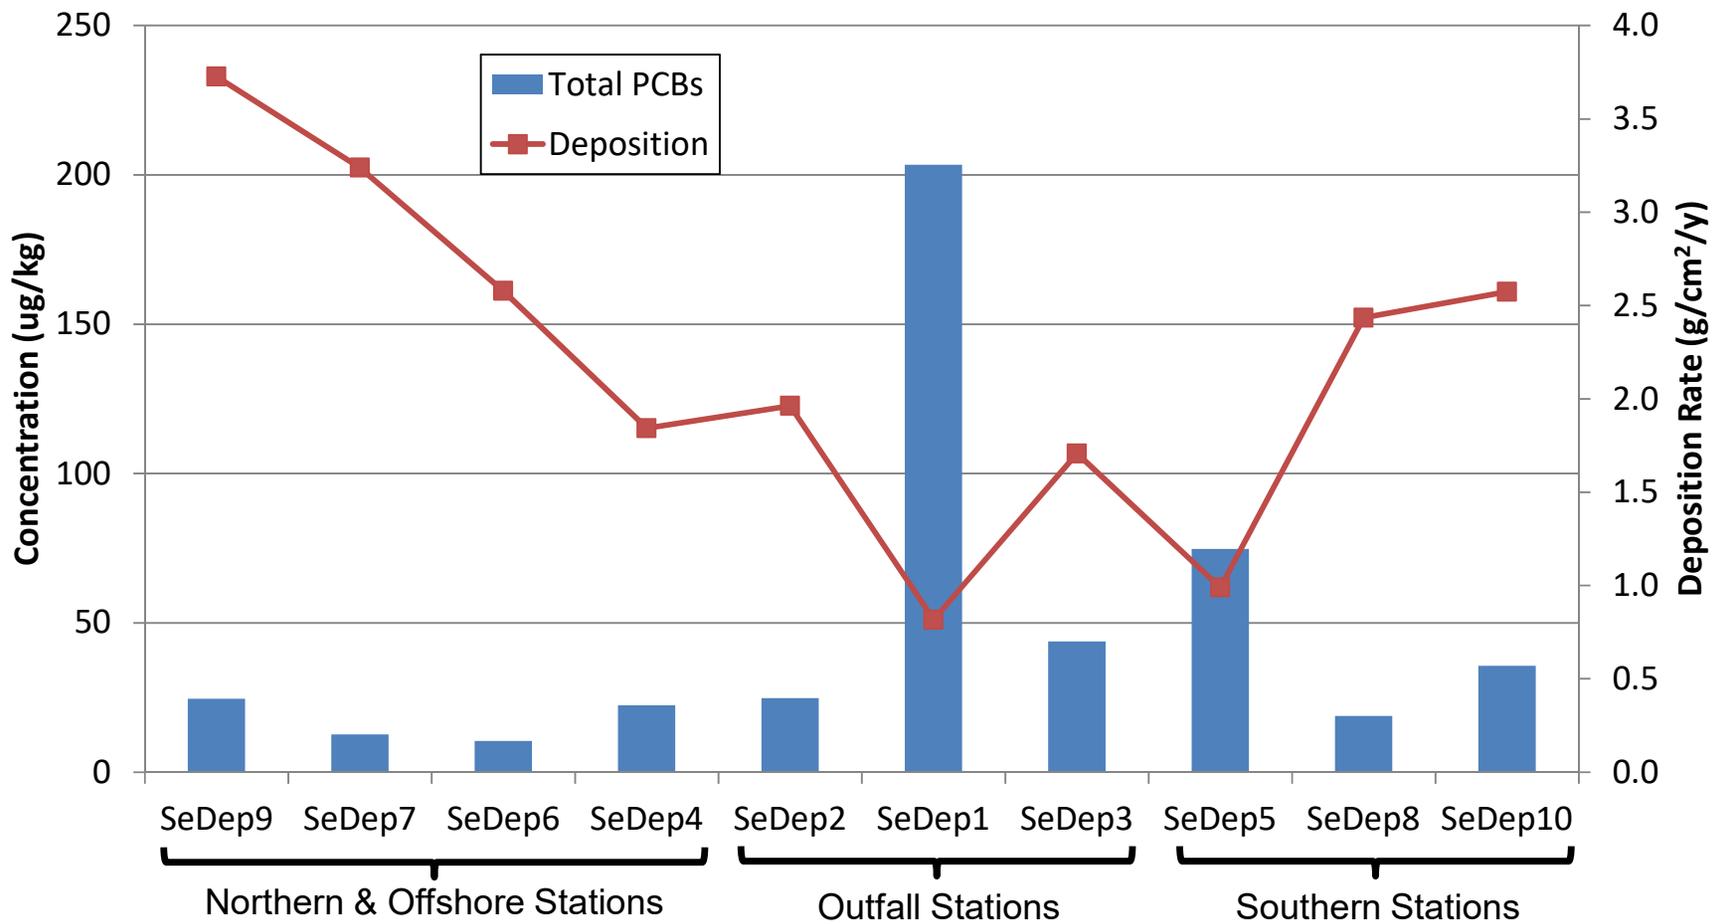

Figure 108. Total PCB concentrations in deposited sediments and deposition rates based on the SeDep sediment traps.

SeDep Sediment Trap and Surface Sediment Chemistry: Samples collected in the sediment traps were analyzed for a subset of chemicals that were determined based on the known risk drivers for the sediments in the vicinity of Oscar Pier. In addition, surface sediment samples from the top 2 cm of the sediment column were collected by diver directly adjacent to the sediment traps and SeDep sensors at the stations shown in Figure 101. For both sets of samples, analytes included TOC, mercury, copper, lead and PCBs (full congener analysis). Stations SeDep1 and SeDep5 had insufficient sample volume in the sediment traps to allow for TOC analysis.

Results for the sediment trap samples are shown in Table 29 and Figure 105 – Figure 108. TOC levels were relatively low and uniform across all samples, ranging from a low of 0.32% to a high of 0.40%. Mercury in the sediment traps ranged from a low of 0.27 mg/kg at station SeDep9, to a high of 1.53 mg/kg at station SeDep5. Depositing particles at three of the stations (SeDep3, SeDep5 and SeDep10) exceeded the site Preliminary Remediation Goal (PRG) for mercury (0.71 mg/kg), suggesting that there is still potential for recontamination of mercury in the area. The pattern of mercury concentrations in the sediment traps was inversely correlated with the deposition rate, with highest mercury concentrations generally occurring at stations with lowest deposition rates. Spatially, northern and offshore stations generally had lower concentrations while outfall and southern stations general had higher concentrations.

Copper concentrations in trap samples ranged from a low of 49.1 mg/kg at station SeDep7 to a high of 119 mg/kg at SeDep5. Concentrations were generally below the PRG for copper (214 mg/kg) at all stations, indicating that copper input levels in the area are not likely to be driving recontamination. As with mercury, the pattern of copper concentrations in the sediment traps was inversely correlated with the deposition rate, with highest levels generally occurring at stations with lowest deposition rates. The spatial distribution of copper inputs into the sediment traps showed highest concentrations in the vicinity of the outfall and to the south, with lower concentrations offshore and to the north. Lead concentrations ranged from 30.8 mg/kg (SeDep8) to 76.4 mg/kg (SeDep1) and followed similar patterns as copper and mercury. Concentrations were generally below the PRG for lead (119 mg/kg) at all stations, indicating that lead input levels in the area are not likely to be driving recontamination.

Concentrations of total PCBs in the sediment traps ranged from 10.4 µg/kg at SeDep6 to 203.4 µg/kg at SeDep1. PCB levels in the traps were also highest at the stations with lowest deposition rates, and particularly high at SeDep1 directly off the outfall. This was the only station with PCB trap concentrations that exceed the PRG (170 µg/kg), suggesting that recontamination was only likely in close proximity to the outfall for PCBs.

Results for the surface sediment samples are shown in Table 30 and Figure 109 – Figure 113 in relation to the trap sediment samples. TOC levels in surface sediments ranged from 0.13% (SeDep1) to 0.36% (SeDep5) with an average concentration of 0.26%. Compared to the sediment trap levels, surface sediment levels were consistently lower at all stations. This is consistent with expectations that the fresher incoming particles would have higher TOC levels than the bed sediments. Mercury levels in surface sediments ranged from a low of 0.29 mg/kg at SeDep1 to a high of 7.55 mg/kg at SeDep10. Surface

sediment concentrations were generally similar to or higher than sediment trap levels, suggesting that even though incoming particulate levels exceed the PRGs in some areas, they are still exerting downward pressure on the surface sediment concentrations. Highest mercury levels were generally found off and to the south of the outfall, and the increasing gradient to the south suggests that sediments to the south of the Oscar Pier area may be a more influential source of mercury than the stormwater outfall. Four stations had surface sediment concentrations exceeding the PRG and three of these corresponded with stations where the sediment trap levels exceeded the PRG (SeDep3, SeDep5 and SeDep10).

Copper concentrations in surface sediments ranged from 41.9 mg/kg (SeDep7) to 426 mg/kg (SeDep4) with an average of about 140 mg/kg. As with mercury, surface sediment concentrations were generally similar to or higher than sediment trap levels, suggesting that incoming particulate levels are still exerting downward pressure on the surface sediment concentrations. In contrast to mercury, highest copper levels were generally found off and to the north of the outfall, and the increasing gradient to the north suggests that sediments to the north of the Oscar Pier area may be a more influential source of mercury than the stormwater outfall. Two stations had surface sediment concentrations exceeding the PRG (SeDep2 and SeDep4).

Lead concentrations in surface sediments ranged from 54.5 mg/kg (SeDep7) to 328 mg/kg (SeDep3) with an average of about 154 mg/kg. As with copper and mercury, surface sediment concentrations were generally similar to or higher than sediment trap levels, suggesting that incoming particulate levels are still exerting downward pressure on the surface sediment concentrations. The spatial distribution of lead in surface sediments showed high concentrations throughout the vicinity of the outfall, falling off to the north and south. Five stations had surface sediment concentrations exceeding the PRG (SeDep1, SeDep2, SeDep3, SeDep4 and SeDep5).

Total PCB levels in surface sediments ranged from a low of 11.4 µg/kg at SeDep6 to a high of 573 µg/kg at SeDep10 with an average of 99.6 µg/kg. As with metals, surface sediment concentrations of total PCBs were generally similar to or higher than sediment trap levels, suggesting that incoming particulate levels are still exerting downward pressure on the surface sediment concentrations. A clear exception to this was at the outfall station SeDep1 where the sediment trap concentration significantly exceeded the surface sediment concentration. Spatially, highest concentrations in surface sediments were generally found in the vicinity of the outfall and to the south of the outfall, particularly at the furthest southern station SeDep10.

Overall, the sediment trap and surface sediment chemistry indicated that incoming sediment particles generally had lower contaminant concentrations than surface sediments, indicating that they should tend to improve conditions over time. However some chemicals including mercury and PCBs had particle input concentrations that still exceed their respective PRGs. Spatial distributions of trap and surface sediments suggest that the chemicals of concern may have different sources that are driving conditions at the site, with some chemicals showing gradients to the south (mercury and PCBs), some showing gradients to the north (copper), and some being fairly evenly distributed off the outfall (lead).

Table 30. Chemistry results for the surface sediment samples collected at the SeDep stations.

| Station | TOC (%) | Hg (mg/kg) | Cu (mg/kg) | Pb (mg/kg) | PCB (ug/kg) |
|---------|---------|------------|------------|------------|-------------|
| SeDep1 | 0.13% | 0.29 | 180 | 136 | 40.6 |
| SeDep2 | 0.35% | 0.44 | 262 | 235 | 61.3 |
| SeDep3 | 0.24% | 1.71 | 139 | 328 | 64.1 |
| SeDep4 | 0.24% | 0.70 | 426 | 288 | 58.3 |
| SeDep5 | 0.36% | 4.53 | 138 | 237 | 127.6 |
| SeDep6 | 0.25% | 0.69 | 42.6 | 57.1 | 11.4 |
| SeDep7 | 0.27% | 0.54 | 41.9 | 54.5 | 12.0 |
| SeDep8 | 0.27% | 0.72 | 45.4 | 64.5 | 32.7 |
| SeDep9 | 0.25% | 0.63 | 44.2 | 55.2 | 15.7 |
| SeDep10 | 0.23% | 7.55 | 78.1 | 87.9 | 572.9 |

5.6.2.3 October 28-29, 2016 DPS Event - Waiau

Tides and Winds: In the absence of strong freshwater discharges, the primary influences on the circulation in Pearl Harbor are tides and winds. The DPS survey at Waiau was conducted during the period from October 28-29, 2016. Tide and wind conditions for the deployment period are shown in Figure 114 relative to the DPS release and tracking period. The tracking took place over a complete diurnal tide cycle with a tidal range of about 0.7 m which is typical for Pearl Harbor. Wind conditions were characterized by relatively weak trade winds with wind speeds ranging from about 5 mph during the night to about 10-15 mph during the day and generally blowing from the ENE direction. Release times for the DPS units started during a period of flood flow, and continued through successive ebb and flood periods. There was no measurable precipitation at the Honolulu gage during the event, however there was precipitation observed at the site during the night of October 28, and likely precipitation in the watershed that fed some flow to the local streams in the area.

DPS Tracking: A total of 20 DPS units were released during the tidal period extending from 10/28/2016 09:00 – 10/29/2016 08:45. Two of the units malfunctioned and did not provide useful data. A total of 18 units successfully completed the full trajectory and bottom contact cycle. The DPS units were all released from approximately the same location off the suspected OWS discharge pipe location in at a water depth of about 1.5 meters. Table 31 summarizes the information on the release positions, times along with the bottom contact times and positions. The releases all occurred at approximately the same location and occurred at about 75 minute intervals with the exception of the two units that malfunctioned resulting in intervals of 150 minutes.

Three-dimensional trajectories for the DPS systems are shown in Figure 115 – Figure 120. The first four DPS units (DPS1-1, DPS2-1, DPS3-1 and DPS4-1) followed a relatively similar trajectory, traveling S or SSW toward the deeper water channel area, and then turning W or WNW in the deeper water where they made bottom contact. These first four units were had release times during the first flood tide condition. The next six units (DPS5-1, DPS6-1, DPS7-1, DPS8-1, DPS1-2 and DPS3-2) also followed a relatively similar trajectory with the exception of DPS8-1. These units all generally traveled S for a short distance before making bottom contact in the shallow water prior to reaching the channel. DPS8-1 followed a similar trajectory but continued S to the channel, and then turned WNS before making bottom contact. These DPS units were released during the time frame spanning the first slack high water, the first ebb tide, and the first slack low water.

The next three DPS units (DPS2-3, DPS4-2 and DPS5-2) followed similar trajectories, traveling initially to the S or SSE to the deeper water, and then turning W or WNW before making bottom contact. These units were release during the second flood tide condition. The subsequent four units (DPS7-2, DPS8-2, DPS6-3, and DPS3-3) had similar trajectories, first traveling SSE, and then turning SW before making bottom contact near the edge of the channel. These units were released during the second ebb tide condition. The final DPS unit (DPS1-3) followed a similar pattern to DPS3-2, traveling S for a short distance before making bottom contact in the shallow water prior to reaching the channel.

A number of useful characteristics can be extracted from the DPS trajectory data including travel distance and speed. These metrics provide insight into the scale and movement associated with the DPS trajectories. Table 32 shows the average speed, total distance traveled, and bottom contact depth for the DPS units in relation to the tide condition at the time of release. Results for travel distance and average speed are also shown in Figure 121 and Figure 122, respectively.

The travel distance results show that particles released from the Waiau release point traveled distances ranging from about 0.25 – 1.1 km with an average distance of about 0.67 km. The average transit speed during the deployment ranged from 2.9 – 5.3 cm/s with an overall average of 3.9 cm/s. Consistent with the observational descriptions of the trajectories above, the DPS units released during the flood tide tended to travel further, faster and make contact in deeper water than those released during slack water or during ebb tide. Table 33 shows the average speed, total distance traveled, and bottom contact depth for the DPS units in relation to the wind condition at the time of release. Values were binned and averaged for conditions less than or greater than the average wind speed for the period of 8.4 mph. Some increase was observed in average speed and total distance traveled during higher wind conditions, while the bottom contact depth was essentially unchanged.

The complete map of trajectories and bottom contact locations is shown in Figure 124. Overall, the trajectories show a consistent pattern of southward travel toward the deeper water in the channel. For the DPS units that reached the channel, the trajectories generally turned toward the west. The overall average speed was 3.9 cm/s, the overall average distance traveled was about 672 m, and the overall average bottom contact depth was about 9.2 m.

Settling Rate and Bottom Contact: The DPS units were programmed to simulate silt sized particle transport with an effective settling rate of 34 mm/min. Results showed that all of the DPS units followed this rate closely. Vertical profiles of the DPS depth versus time and the bottom contact depth are shown in Figure 86. The profiles show the uniform settling rate for all DPS units. Bottom contact depths ranged from about 4.5 m for DPS 3-2, to a high of 11.6 m for DPS 2-1, with an average of 9.2 m. These results suggest that the DPS units can function effectively over the expected range of depths for harbor environments. Because the settling rates were uniform, bottom contact times varied as a function of the contact depth. Settling times varied from a low of 2.2 hours for DPS 3-2, to a high of 5.7 hours for DPS 9-1, with an average of 4.5 hours.

The spatial distribution and footprint of bottom contacts are shown in Figure 124 and Figure 125. Two qualitative footprint areas were defined including the footprint that encompassed only the bottom contact locations, and a broader footprint that encompassed the trajectories and the bottom contacts. The first footprint is descriptive of the likely deposition area for silt-sized particles released from the Waiau release point. The second footprint is representative of silt and large (faster settling) size particles based on the assumption that these particles would settle somewhere along the trajectory leading to the bottom contact location for silt.

The distribution was separated roughly into two groups including a group that made bottom contact in the shallow water relatively close to the outfall (1-2, 1-3, 3-2, 5-1, 6-1

and 7-1), and a group that was transported south and west toward the navigation channel (all others). While not supported by statistical replication, these results suggest that silt-sized particles discharged from the suspected OWS outfall near Waiau are most likely to either settle in the shallow water due south and near the outfall, or be swept further south and west into the navigation channel. By percentage, 33% settled near the outfall, and 67% were transported and settled further out of the harbor.

The overall spatial scale and area of the footprint were estimated based on the root-mean-square distance from the bottom contact cluster centroid, and the mean-square distance from the bottom contact cluster centroid, respectively. The length scale of the footprint based on this method was about 0.92 km, and the area was about 0.84 km². Compared to the release in the deeper water at Oscar Pier, these spatial scales are relatively small and indicate that for silt particles, the footprint associated with a discharge from the Waiau release point is constrained within the general vicinity of the outfall. The results indicate that the likely area of deposition for particle bound contaminants released from or resuspended near the suspected OWS outfall would have been to the south and southwest of the release point. This was essentially true under all release conditions for tides and winds spanning typical conditions observed in the East Loch of Pearl Harbor. None of the DPS tracking units were observed to transit over or make bottom contact in the area of DU E-2 (Figure 125). Based on these results, it appears unlikely that a release from the suspected OWS discharge location would have resulted in transport and deposition of particle bound contaminants to the area of DU E-2.

Overall, the GPS tracking and bottom contact data collected using the DPS systems provided a clear visualization of the area of the harbor with connectivity to the outfall, the depth, spatial and time scales of the transport area, and the spatial location and size characteristics of the deposition footprint. These are all key aspects in understanding the complex nature and extent of the particle transport associated with discharge from a given outfall location.

DPS Sensor Data: Sensors mounted on the DPS units recorded temperature and salinity continuously during the Oct 28-29, 2016 survey event. The primary purpose of the sensor measurements was to document conditions during the deployments and demonstrate that the system can accommodate sensors of this type. The temperature and salinity data would be more relevant during an actual storm event. In addition, sensors such as transmissometers or optical backscatter sensors would also be useful during storm event deployments. For the non-storm deployments that were conducted here, the sensors primarily provide background information on site conditions. Results for the sensor data are described below.

Salinity and temperature data for the DPS sensors are shown in Figure 126 and Figure 127, respectively. Of the 18 tracking events, sensor data were successfully collected during all 18. In general, the salinity data were relatively uniform throughout the survey with some freshening of the surface waters during the later deployments. While no measurable precipitation was registered at the Honolulu gage, there was precipitation at the site during the night of October 28, and likely there was rain in the watershed to the north as well that fed some flow to the local streams (Waimalu and Kalauao drain into the area). This is the likely source of the observed freshening. Temperature data were also relatively uniform through the survey event. Some cooling was observed in the shallower

waters during the night, and some warming was observed in relation to the fresher surface water during the later deployments. In general, the results illustrate that the DPS system can act as a platform for sensors to track background or storm event conditions during the trajectories of the drifters.

Table 31. DPS release and bottom contact times and positions for the October 28-29, 2016 DPS survey event.

| DPS Unit | Release | | | Bottom Contact | | |
|----------|------------------|--------------------------|-------------------------|------------------|--------------------------|-------------------------|
| | Date-Time | Longitude (deg NAD83) | Latitude (deg NAD83) | Date-Time | Longitude (deg NAD83) | Latitude (deg NAD83) |
| DPS1-1 | 10/28/2016 09:00 | -157.95765 | 21.38361 | 10/28/2016 14:25 | -157.96242 | 21.37825 |
| DPS2-1 | 10/28/2016 10:15 | -157.95778 | 21.38361 | 10/28/2016 15:57 | -157.96109 | 21.37822 |

6 PERFORMANCE ASSESSMENT

Performance analysis focused on the ability of the systems to provide improved exposure, transport and fate assessment for stormwater sources in a cost effective manner. A key aspect of this performance was the ability to improve our understanding of the linkage between this ongoing sources and potential recontamination of sediment. This requires the ability to accurately track the trajectory of the plume and associated particle-bound contaminants, and establish reliable measures of event-based depositional footprints. Performance was measured against performance criteria established in the demonstration plan. Performance objectives for the three technologies are summarized in Table 4 – Table 5.

6.1 Drifting Exposure System

For the DrEx system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on tracking accuracy, communications reliability, water sampler performance, and system survivability. Tracking accuracy of the GPS system is important to reliable measurements of the plume trajectory. It is important that the GPS tracking operate within specified accuracy under field conditions. To evaluate this quantitatively, we conducted verification measurements with a highly accurate GPS unit during field deployments. Our expectation was that the GPS would provide accuracy as measured by the difference between the drifter GPS and the verification GPS that was <5 m for >90% of the deployment period. Reliable data communications are important to the performance of the system in active harbor areas because they allow for real-time tracking without having to utilize extensive boats and crews to follow the drifters. Communications are also important for any modifications to the sampling and for final location and retrieval of the system. Our expectation for communications reliability was that the telemetry link data would provide reliable transmissions >90% of the deployment period. An important aspect of the DrEx system is its ability to collect samples during the deployment period. Reliable sample operations are reflected in the proper collection of composite sample volumes based on the programming of the system. Our expectation for the water sampler on the DrEx was that it would collect a reliable composite sample with total volume within 10% of target during the deployment period. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is a key performance metric for the systems. Survivability in this case refers to successful mission completion, without major system failures or lost units during field deployments. Our expectation was for >80% survivability under field conditions.

The primary qualitative performance object for the DrEx was that the drifters reliably track the surface plume of a stormwater discharge release. While this is difficult to determine quantitatively, a number of methods will be used to give a quantitative assessment of the plume tracking performance including onboard salinity and temperature measurements, and plume tracking measurements made with water quality instruments from the survey boat during the discharge event. Our expectations are that onboard salinity and temperature signature will be consistent with plume characteristics, and that DrEx trajectories will be consistent with spatial surface plume mapping results.

6.2 Drifting Particle Simulator

For the DPS system, we established a series of quantitative and qualitative performance objectives similar to the DrEx but adapted to the particle tracking capability of the system. Quantitative objectives focus on tracking accuracy, communications reliability, settling rate performance, and system survivability. Tracking accuracy of the GPS system is important to reliable measurements of the plume trajectory. It is important that the GPS tracking operate within specified accuracy under field conditions. To evaluate this quantitatively, we will conduct verification measurements with a highly accurate GPS unit during both pier-side testing and field deployments. Our expectation is that the GPS will provide accuracy as measured by the difference between the drifter GPS and the verification GPS that is <5 m for >90% of the deployment period. Reliable data communications are important to the performance of the system in active harbor areas because they allow for real-time tracking without having to utilize extensive boats and crews to follow the drifters. Communications will also be important for any modifications to the sampling and for final location and retrieval of the system. Our expectation for communications reliability is that the telemetry link data will provide reliable transmissions >90% of the deployment period. An important aspect of the DPS system is its ability to simulate the effective rate of settling for discharge related particles during the deployment period. Reliable settling rates are reflected in the depth data from pressure sensor onboard DPS . Our expectation is that the effective settling rates will be accurate to within 10% of target rate during the deployment period. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is a key performance metric for the systems. Survivability in this case refers to successful mission completion, without major system failures or lost units during field deployments. Our expectation is for >80% survivability under field conditions.

The primary qualitative performance object for the DPS is that the drifters reliable track the particle plume of a stormwater discharge release. While this is difficult to determine quantitatively, a number of methods will be used to give a quantitative assessment of the plume tracking performance including onboard turbidity sensor data, and particle tracking data from ADCP and profiled sensors on the survey boat. Our expectations are that onboard turbidity signature will be consistent with particle plume characteristics, and that DPS trajectories will be consistent with spatial surface and subsurface particle plume mapping results.

6.3 Sediment Deposition Detector

For the SeDep system, we established a series of quantitative and qualitative performance objectives. Quantitative objectives focus on deposition detection sensitivity, measurement reliability, and system survivability. Detection sensitivity is important because the goal is to be able to detect relatively small events associated with individual storm related deposition as well as longer term accumulation associated with multiple events. To evaluate this quantitatively, we will utilize data from controlled tank testing and field deployments including the sediment traps. The goal will be to achieve sensitivity <1 mm of deposition for typical particle sizes in the silt to sand range and comparable deposition to short term trap results. Measurement reliability is important because the sensors will be

largely unattended and if they are not reliable then the deposition events may not be captured in the data. To evaluate this quantitatively, we will use differential pressure data from field deployments. Our goal is to achieve reliable pressure data collected >90% of the deployment period. Because of the unattended nature of the systems and the complex, harsh and active areas where they will be deployed, survivability is also a key performance metric for the systems. Survivability in this case refers to successful mission completion, without major system failures or lost units during field deployments. Our expectation is for >80% survivability under field conditions.

The primary qualitative performance object for the SeDep is that the system be reasonably easy to use in the field. Overly complex or difficult to deploy systems incur higher costs and are less likely to be adopted at actual sites. To evaluate this, we will focus on ease of installation and retrieval which will be measured based on feedback from the dive team and the ability to install or retrieve a typical system array within a reasonable time period of 1-2 days.

6.4 Quantitative Performance Objectives – Drifting Exposure System

6.4.1 Tracking Accuracy

6.4.1.1 Description

The DrEx system utilizes an SBAS-corrected onboard GPS to provide accurate tracking of its location and the trajectory of the stormwater plume. The system uses a 12 channel GPS receiver and records position to 0.001 minute of latitude and longitude (1.8 meters). Absolute accuracy of the position is expected to be better than 15 meters worldwide. In areas served by one of three SBAS system (WAAS in North America, EGNOS in Europe, and MSAS in East Asia) absolute accuracy is expected to be better than 3 meters 2DRMS. Tracking accuracy thus provides a measure of how well the DrEx GPS system represents the true location of the unit in the environment and the location of the plume.

6.4.1.2 Data Collection

GPS accuracy data and statistics were collected during field deployments at Paleta Creek in San Diego Bay. Two methods were used including following the drifters in a small boat a marking their positions with a pole-mounted sub-meter GPS (Trimble Geo-XT), or by mounting a secondary sub-meter GPS (Bad Elf GNSS Surveyor) directly on the DrEx unit and recording positions continuously. The pole-mounted GPS method was less accurate due to the need to try to position the GPS antenna over the DrEx unit from a moving boat during storm conditions.

6.4.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period provided that the SBAS differential system was active. The data were interpreted by first determining if the drifter status indicated a differential GPS fix, and then time-matching the data from the DrEx GPS and the verification GPS. Position differences were then calculated for each verification point. A difference histogram was then developed and the position difference at the 90th percentile of the histogram was used to compare to the performance objective. This was repeated

for each of the verification techniques (Trimble and Bad Elf), and also for each of the survey events. The results are summarized in Table 34.

Results based on the Trimble GeoXT GPS measurements showed 90th percentile differences of 4.9 m and 6.4 m for the Jan 5-6, 2016 event and Feb 1 event, respectively. Results from the BadElf GNSS GPS measurements showed 90th percentile differences ranging from 5.4-5.5 m for the Jan 5-6, 2016 event, and 5.0-5.6 m for the Feb 1, 2016 event. While these values and ranges generally slightly exceeded the performance objective, the objective was considered to be met because the results were generally both very consistent and also very close to the objective. The 5 m objective was originally chosen on the basis that this was an approximate level at which the drifter tracking accuracy would be suitable for small-scale plume tracking around outfalls and urban embayments. The ranges of tracking accuracy measured during the survey events appears to consistently be adequate to achieve this original objective. In addition, the drifter firmware is being updated to improve the resolution of the recorded GPS positions to match the resolution of the Garmin GPS engine that is used onboard the drifters. This will improve the resolution by a factor of ten, and may further improve the tracking accuracy of the systems.

6.4.2 Communications reliability

6.4.2.1 Description

The DrEx system uses the Iridium satellite system to communicate positions and other status and sensor data to the user via the internet. The frequency of this communication is a user-selectable variable during the setup of the system and depends on two settings. First, the sampling interval (in seconds) of the DrEx unit is set, which determines how frequently data will be recorded onboard the unit. Second, the recurrence interval for Iridium transmission (in recorded positions) is set, which determines how frequently positions will be transmitted. The data transmission interval is thus equal to the product of the sampling interval and the recurrence interval.

6.4.2.2 Data Collection

Telemetry link data and statistics for the DrEx were collected during the field deployments at Paleta Creek. For these deployments, the sampling interval was set to 15 seconds, and the recurrence interval was set for 20 positions, so the data transmission interval was about 300 seconds (5 minutes). The telemetry data were sent to and stored on the Brightwaters internet server at <http://www.brightwaters.com/vas/SPAWAR/>. These files were downloaded during the deployment using a MatLab script that automatically queried the server and plotted the DrEx unit positions on a map. At the end of each deployment, the final data file was downloaded from the server, and these data were used to examine the communications reliability.

6.4.2.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. The data were interpreted by determining the total number of possible data transmissions at the specified data transmission interval for each deployment. The actual number of data transmissions was then determined from

the final data files that were downloaded from the server. The transmission success rate was then calculated as the actual transmissions divided by the possible transmissions for comparison to the performance objective. To accommodate typical variability in the transmission time, the transmission was considered to be successful if the period between transmissions was less than twice the specified transmission period.

Results for communications reliability were evaluated for each of the two survey events (Table 35). During the Jan 5-6, 2016 event, communications reliability ranged from a low of 59% to a high of 94%, with an overall average of 81%. During the Feb 1, 2016 event, reliability ranged from 34% to 100% with an overall average of 77%. While these levels fall somewhat short of the performance goal, experience during the events indicated that the communications reliability was generally sufficient to provide adequate information on the locations of the drifters throughout the deployments, as well as providing accurate information on the location for the retrieval. In general, drifters with low communications reliability had often become trapped near the pier structures, or between a ship and the pier, and thus satellite communications were hampered by interfering structures. Overall, it appears that a realistic expectation for communications reliability under these types of conditions is in the range of 80%, and that performance in this range should be adequate to support the requirements of the system.

6.4.3 Water sampler operation

6.4.3.1 Description

A novel aspect of the DrEx system is its ability to collect composite samples while tracking the trajectory of the stormwater plume. This capability allows for simultaneous tracking and exposure quantification. To enable this, the DrEx system utilizes a low-flow peristaltic pump controlled by the DrEx unit, and connect to a 5 liter sampling bag that contains the sample. The pump is programmable so that the sampling rate can be set by the user, along with the maximum sample volume and a range of other parameters. The pump is calibrated prior to deployment so that the sample volume collected should correspond closely to the programmed value.

6.4.3.2 Data Collection

Water sampler operation data were collected during the field deployments at Paleta Creek. Data collection included the volume counts recorded by the DrEx unit at each recording interval, along with the final total volume contained in the sampling bag. The DrEx pump data were converted to flow using the pump calibration data. The total volume in the sampling bag was determined by pre- and post-deployment weights of the sample bag, with the water volume calculated as the difference between these two weights divided by the density of water.

6.4.3.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate reliable composite sample with total volume within 10% of the user specified target. The data were interpreted by calculating the cumulative pumping volume based on the DrEx recorded data, and the total volume based on the pre- and post-deployment weights. The difference between

these volumes was then divided by the actual volume to determine the percent difference, and this was compared to the performance objective.

Results for water sampler operations were evaluated for each of the two survey events (Table 36). For the Jan 5-6, 2016 event, percent differences between the pump estimated volume and the measured volume ranged from 14% to 100% with an overall average of 41%. Large differences were primarily attributable to leaks that developed in the sampling bags after retrieval of the drifters. These leaks resulted in water loss prior to the weighing of the bags for the final volume determinations. In addition, one of the bags inadvertently became disconnected from the sampling tube and so no volume flowed into the bag. Considering only the units that were operational and had no leaks, the percent difference had an average of 14%.

For the Feb 1, 2016 event, percent differences ranged from a low of 1% to a high of 91% with an overall average of 20%. Prior to this event, outer sleeves were added to protect and support the sampling bags. Only one sampling bag developed a leak during this event (DrEx 109). Eliminating this unit from the analysis, the average percent difference was found to be 12%. In general, for operational units with no leaks, the performance of the sampling system provided good agreement with the post-survey volume measurements within the range of about 12-14%. While this is slightly higher than the 10% target, it is still adequate to achieve the sampling requirements for the system.

6.4.4 System survivability

6.4.4.1 Description

The DrEx units are designed to be deployed in harbor and coastal areas during storm events. Weather conditions during these events are often extreme, with high winds, rainfall, and waves generated by the storms. Debris, obstructions and ship traffic are also have the potential to damage the systems. The cost of performing the surveys can be significantly impacted if a large number of units are lost during the event. For these reasons, system survivability is an important metric for the DrEx systems.

6.4.4.2 Data Collection

System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Paleta Creek. Data collected included the total number of systems deployed, the number that completed the mission successfully, the mode of system failure for those that didn't, the number of systems damaged during the deployment and the nature of the damage, and the number of systems lost during the deployment and the circumstances of the loss.

6.4.4.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). The difference between the number of deployed systems and the number of successful systems was divided by the number of deployed

systems to calculate the success rate. The success rate was then compared to the performance objective.

Results for system survivability were evaluated for both survey events. Results are summarized in Table 37. For the Jan 5-6, 2016 event, no drifters were lost or sustained major damage. One drifter (109) failed due to a faulty mounting bracket that caused the magnetic switch to deactivate and shutdown the system. This only required a minor repair. For the Feb 1, 2016 event, no drifters were lost or sustained major damage. One drifter (112) lost its conductivity/temperature sensor. The same drifter also had some saltwater flooding to the pump housing for the water sampler. The total damage was estimated to be less than 25% of the drifter value. Overall, the performance objective for system survivability was met because no drifters were lost or sustained major damage.

6.5 Qualitative Performance Objectives – Drifting Exposure System

6.5.1 Surface plume tracking effectiveness

6.5.1.1 Description

The DrEx system was designed to provide a method for tracking and sampling the surface plume associated with stormwater discharges. These plumes have complex dynamics associated with the momentum and buoyancy of the plume, and the interaction with ambient tides, currents, winds and waves. The ability of the system to track the plume is important in resolving the plume trajectory under these complex conditions. In addition, the sampling system onboard the DrEx units provides a means of sampling these plumes under real-world conditions. In order for these samples to be meaningful, the system must maintain contact with the plume as it travels and disperses in the ambient environment.

6.5.1.2 Data Collection

DrEx GPS trajectory data, onboard salinity and temperature sensor data, and survey boat collected plume tracking data (to the extent possible) were collected during the DrEx field deployments at Paleta Creek. GPS data from the DrEx units was recorded onboard each drifter as well as being stored on the web server. The GPS provided information regarding the position of the DrEx unit relative to the plume. Temperature and salinity were recorded onboard each drifter as well using a self-recording temperature/conductivity sensor (model Hobo U24) attached to a bracket on the main hull of the drifter. The temperature and salinity data provided a means of gaging if the drifter was still in the plume based on the differential in temperature and salinity between the incoming stormwater and the ambient water. We also used a hull-mounted water quality meter and a GPS unit on the survey boat to occasionally run transects to determine the location of the plume based on surface water characteristics. All of these measures were expected to be qualitative due to the complex nature of the plume dynamics, and the dissipation of the plume over time following discharge. Because site specific plume data were collected, we did not perform modeling simulations as a verification measure, however it is anticipated that simulations for these events will be conducted in the future as part of SERDP project ER-2428 (results were not available at the time of publication of this report).

6.5.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this qualitative performance objective was to demonstrate that the DrEx units generally tracked the stormwater plume based on the onboard salinity and temperature signature being consistent with plume characteristics. The data were interpreted based on best professional judgement by evaluating the three lines of evidence described above to determine the extent to which the DrEx unit appeared to track the surface plume of the stormwater following discharge.

For the Jan 5-6, 2016 event, we evaluated plume tracking based on the onboard sensors and vertical profiles collected along axial transects through the plume at three different time points during the storm. Analysis focused on the salinity data because it provided the clearest indicator of the stormwater plume. Onboard sensor data were available for all

ten drifters (including 109 which did not record position data). Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. Values were generally low and then rose within the first hour of transport. Values then stabilized for the drifters that traveled to the next pier area to the south. For the drifters that stayed within the Paleta Creek pier area, the salinities tended to drop again as the drifters re-entered the area of the creek mouth. These variations were explained based on the plume dynamics and tidal influences. The vertical profile transects also indicated that the drifters generally stayed within the plume.

For the Feb 1, 2016 event, we evaluated plume tracking based on the onboard sensors and surface water mapping conducted at one time point during the storm event. Analysis focused on the salinity data because it provided the clearest indicator of the stormwater plume. Onboard sensor data were available for nine out of ten drifters (drifter 112 sensor was lost). Salinity data from the onboard sensors indicated that the drifters generally stayed within the plume. Values were generally low and then rose gradually over the first 1-3 hours of transport. Values then stabilized for some drifters, but showed variability for. These variations were explained based on the plume dynamics and tidal influences. The surface water mapping transect also indicated that the drifters generally stayed within the plume (Figure 128).

Overall, the performance evaluation for the surface plume tracking effectiveness indicated that the success criteria were met. Multiple lines of evidence during multiple storms of different magnitudes consistently showed that the drifters stayed within the stormwater plume.

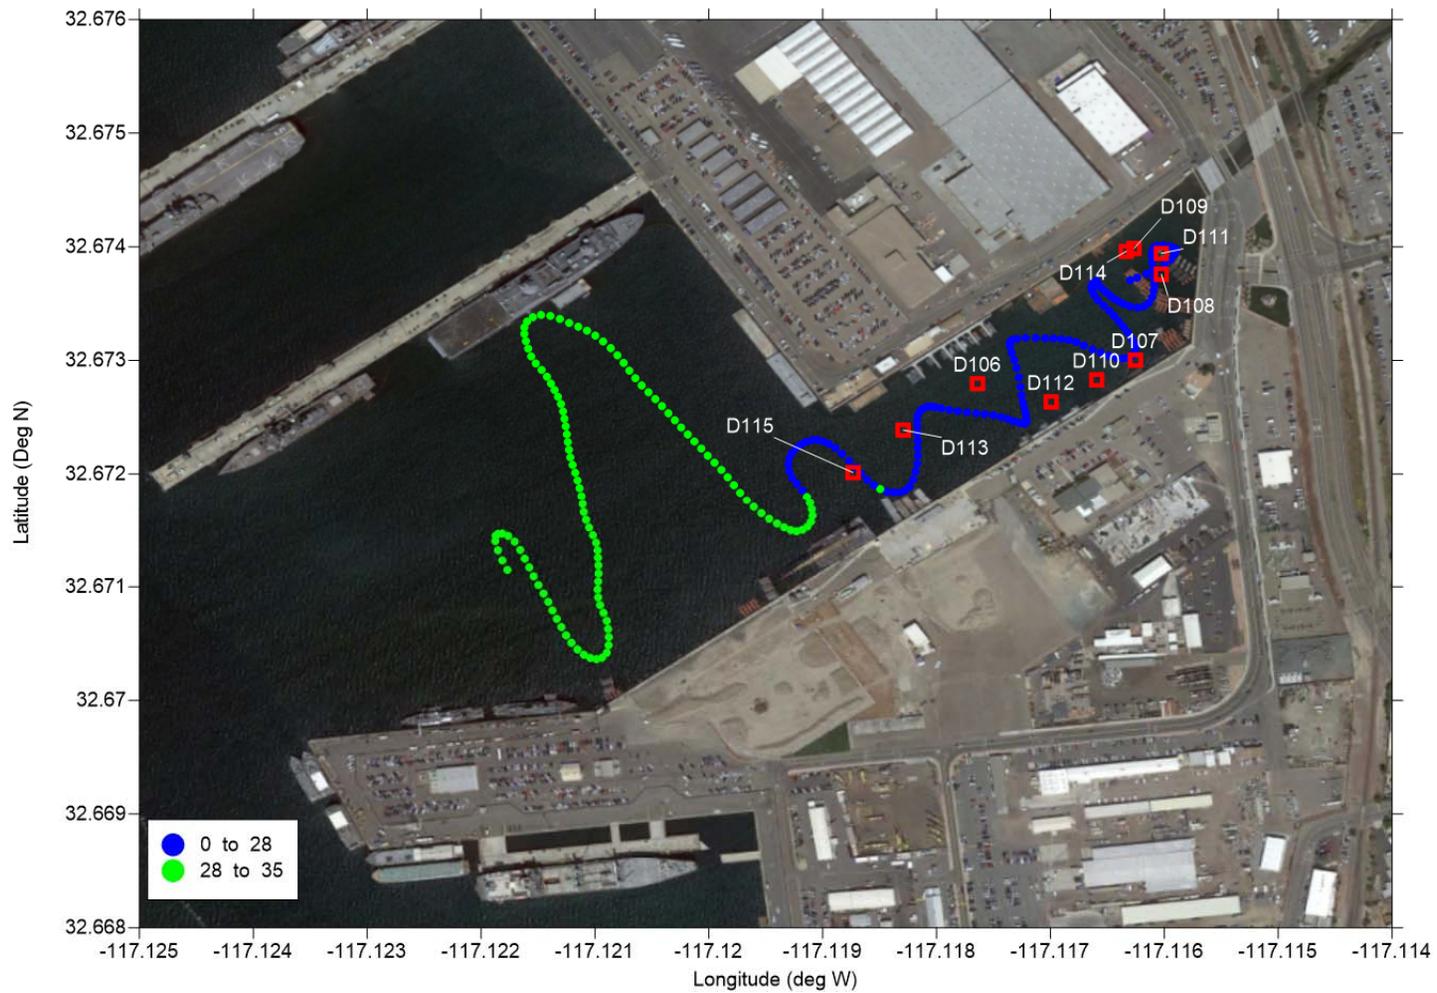

Figure 128. DrEx drifter locations relative to the stormwater plume surface salinity as mapped during the Feb 1, 2016 storm event.

6.6 Quantitative Performance Objectives – Drifting Particle Simulator System

6.6.1 Tracking Accuracy

6.6.1.1 Description

The DPS system utilizes an SBAS-corrected onboard GPS to provide accurate tracking of its location and the trajectory of the stormwater plume. The system uses a 50 channel GPS receiver and records position to 0.000001 degrees of latitude and longitude (0.11 meters). In areas served by one of three SBAS system absolute accuracy is expected to be about 2.0 meters (CEP 50%). Tracking accuracy thus provides a measure of how well the DPS GPS system represents the true location of the unit in the environment and the location of the plume.

6.6.1.2 Data Collection

GPS accuracy data and statistics were collected during field deployments at Pearl Harbor. Data were collected by following the drifters in a small boat a marking their positions with a pole-mounted sub-meter GPS (Trimble Geo-XT).

6.6.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate that the tracking accuracy was <5 m for >90% of the deployment period. The data were interpreted by first time-matching the data from the DrEx GPS and the verification GPS. Position differences were then calculated for each verification point. A difference histogram was then developed and the position difference at the 90th percentile of the histogram was used to compare to the performance objective.

For the March 12-13, 2016 event at Oscar pier, a total of 62 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 3.4 m. For the October 28-29, 2016 event at Waiau, a total of 28 verification measurements were collected with the Trimble Geo-XT. The 90th percentile difference in the position between the DPS and the Trimble was 4.8 m. The results indicate that the success criteria for the DPS tracking accuracy performance objective was met. Results are summarized in Table 38.

6.6.2 Communications reliability

6.6.2.1 Description

The DPS system uses the Iridium satellite system to communicate positions and other status and sensor data to the user via the internet. The frequency of this communication is set at five minutes.

6.6.2.2 Data Collection

Telemetry link data and statistics for the DPS were collected during the field deployments at Pearl Harbor. For these deployments, the data transmission interval was about 300 seconds (5 minutes). The telemetry data were sent to and stored on the Pacific Gyre internet server at www.pacificgyre.com. These files were downloaded during the deployment and viewed on the online mapping tool available on the Pacific Gyre website.

At the end of each deployment, the final data file was downloaded from the server, and these data were used to examine the communications reliability.

6.6.2.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate reliable position data transmitted for >90% of the deployment period. The data were interpreted by determining the total number of possible data transmissions at the specified data transmission interval for each deployment. The actual number of data transmissions was then determined from the final data files that were downloaded from the server. The transmission success rate was then calculated as the actual transmissions divided by the possible transmissions for comparison to the performance objective.

Results for communications reliability are shown in Table 39. For both DPS survey events, the communications reliability averaged 100%. Thus the success criteria for this performance objective was met.

6.6.3 Settling Rate

6.6.3.1 Description

The DPS system simulates particle settling using an underwater micro-winch to mimic the settling velocities of particles by automatically adjusting the depth of subsurface drogue relative to the surface float. The winch is programmed by the user to pay out line at a user-selectable rate in the range of typical particle settling rates. The winch incrementally pays out the line at this rate, lowering the subsurface drogue while sensing the drogue's depth in the water. Settling rate is thus a key performance parameter for the DPS system, and verification that the programmed rates can be achieved under field conditions is important to the acceptance of the technology.

6.6.3.2 Data Collection

Settling rate data were collected from the pressure sensor onboard the DPS units. The pressure sensors are calibrated to output water depth, and are part of the overall data set collected by the micro-winch component of the DPS system. The output also includes a time stamp to allow rate calculations.

6.6.3.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal of this performance objective was to demonstrate accurate settling rates within 10% of target rate. The actual settling rate was calculated from the DPS micro winch pressure sensor as the slope of the time versus depth relationship prior to the unit making bottom contact. The percent difference from the target was then calculated by calculating the difference between the two rates, dividing by the target rate, and multiplying by 100%.

Results for the settling rate measurements are shown in Table 40. The target settling rate for both survey events was 34 mm/min. For both events, the average percent difference from the target settling rate was less than 0.0%. Thus the success criteria for the settling rate performance objective was met.

6.6.4 System survivability

6.6.4.1 Description

The DPS units are designed to be deployed in harbor and coastal areas where exposure to harsh conditions is likely. The cost of performing the surveys can be significantly impacted if a large number of units are lost during the event. For these reasons, system survivability is an important metric for the DPS systems.

6.6.4.2 Data Collection

System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. Data collected included the total number of systems deployed, the number that completed the mission successfully, the mode of system failure for those that didn't, the number of systems damaged during the deployment and the nature of the damage, and the number of systems lost during the deployment and the circumstances of the loss.

6.6.4.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). The difference between the number of deployed systems and the number of successful systems was divided by the number of deployed systems to calculate the success rate. The success rate was then compared to the performance objective.

Results for system survivability were evaluated for both survey events. Results are summarized in Table 41 and Table 42. For the Mar 12-13, 2016 event, no DPS units were lost, and one DPS unit sustained major damage. The damaged unit (DPS3) resulted from an operator error associated with failing to replace the vent plug on the winch. This resulted in flooding of the winch electronics, requiring a complete rebuild of the winch. System survivability for this event was thus 90%. For the Oct 28-29, 2016 event, no drifters were lost or sustained major or minor damage. System survivability for this event was thus 100%. Overall, the performance objective for system survivability was met.

6.7 Qualitative Performance Objectives – Drifting Particle Simulator System

6.7.1 Particle plume tracking effectiveness

6.7.1.1 Description

The purpose of the DPS system is to simulate the trajectories of settling particles in complex hydrodynamic environments and identify the spatial footprint of deposition that is linked to a specific discharge or release point. For this reason, the ability of the systems to track a particle plume is a key objective of the technology.

6.7.1.2 Data Collection

Data on plume tracking was originally expected to be collected in the field when the DPS units were released during stormwater discharge events. However, the logistics of releasing the units during events proved to be difficult with limited storm events, long-distance travel to Pearl Harbor and obtaining permission for releases on short notice at the installations. As an alternative, we collected the DPS trajectory data during the field demonstrations in Pearl Harbor, and then compared those results to simulations from the available hydrodynamic model for releases at the same locations under the same conditions.

6.7.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to show that DPS units provide a qualitatively similar estimate of particle trajectories and deposition footprints as other available approaches. The hydrodynamic model CH3D or EFDC was used to perform simulations for the two demonstrations and the resulting distributions were compared to the DPS results to determine if there was a qualitative agreement in the patterns of deposition resulting from the two methods.

Results for the comparison between the CH3D modeled deposition pattern, and the DPS bottom contact locations are shown in Figure 129 for the Mar 12-13, 2016 event. The two methods show good agreement, with the DPS bottom contacts generally falling within the areas where the CH3D model showed the majority of deposition associated with silt particle release from Oscar Pier. While the model showed some deposition at distances beyond the observed bottom contact locations, the magnitude of deposition in those areas was generally quite low. Thus the DPS units appear to be in good qualitative agreement with the modeled results. Similar results were found for the Oct 28-29 event (public release of the model results were not available at the time of publication of this report). On the basis of these qualitatively similar results, we concluded that the success criteria for this performance objective was met.

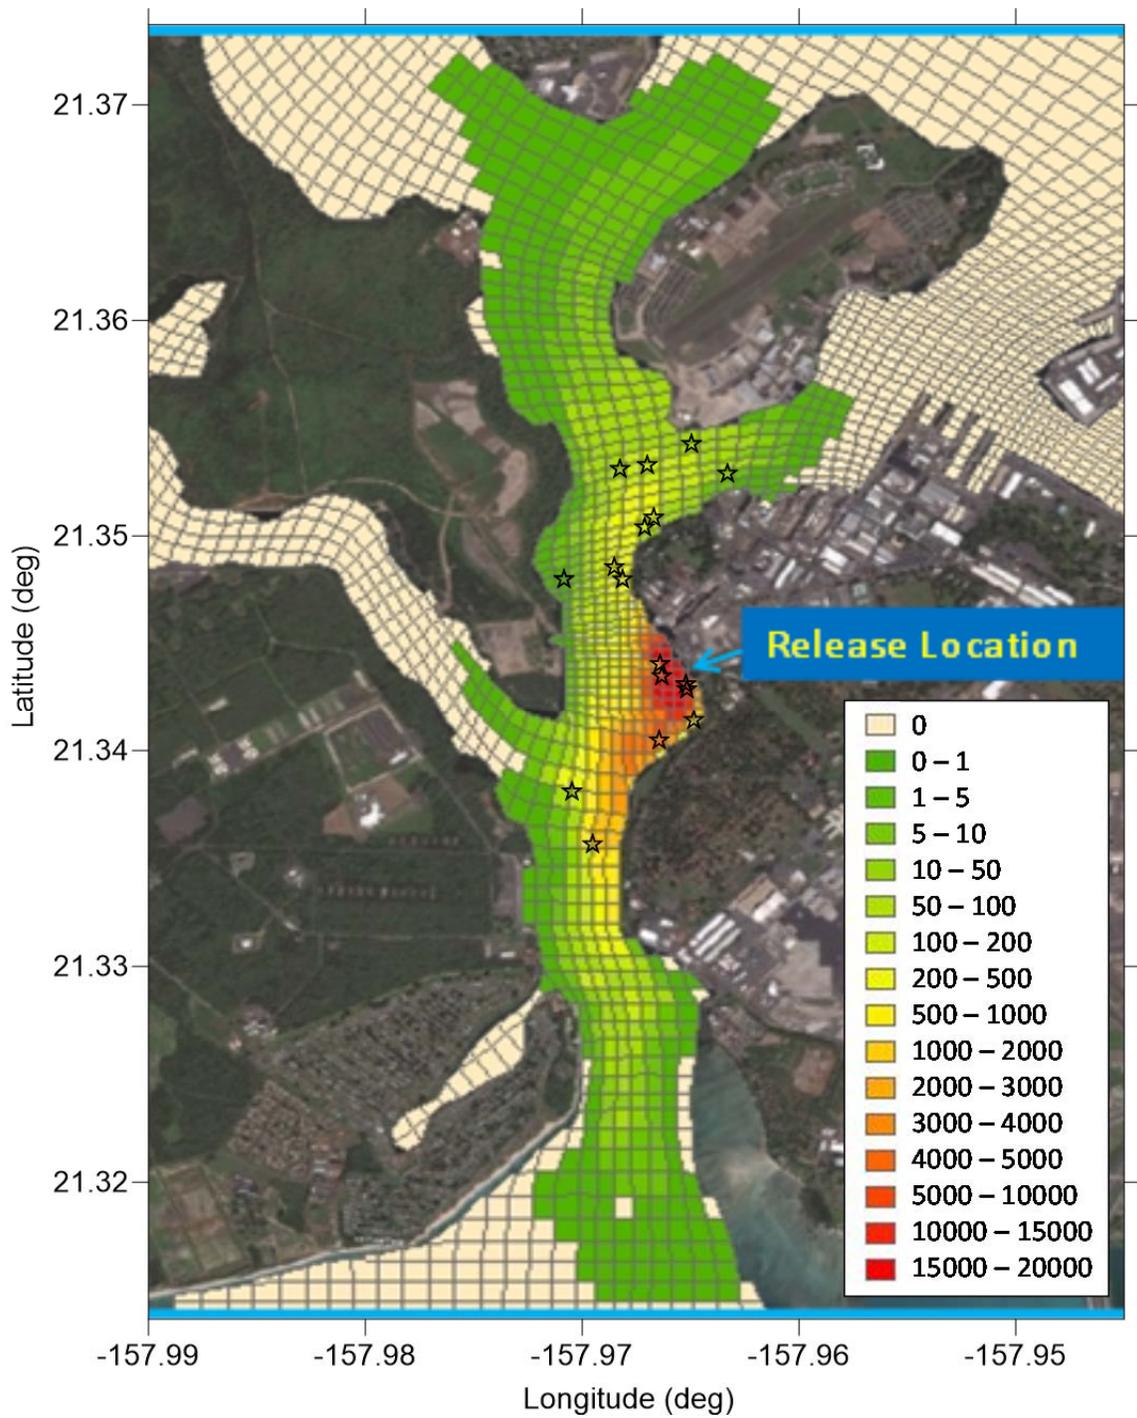

Figure 129. Comparison of modeled deposition and DPS bottom contact locations for the Mar 12-13 event at Oscar Pier. Model deposition units are in grams.

6.8 Quantitative Performance Objectives – Sediment Deposition Detector

6.8.1 Deposition Detection Sensitivity

6.8.1.1 Description

The SeDep uses a precision differential pressure sensor to detect sediment deposition and scour. The application of the system to evaluate event-based deposition related to stormwater or other releases requires a high degree of sensitivity because individual events may be of relatively small magnitude. The detection sensitivity is thus an important metric for the performance of the system.

6.8.1.2 Data Collection

To quantitatively test the sensitivity of the system in the lab, SeDep units were submerged in a test tank and known weights were added to the pressure plate in the form of thin sheets of rubber. Each weight was measured dimensionally and weighed on an independent scale to determine its weight in air and in water. Sensor data were recorded for a period of about 5 minutes to evaluate the variability of the measurement for each weight condition. The slope of the pressure sensor voltage response versus the added weight was also used to calibrate each SeDep system.

6.8.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate that the sensitivity of the SeDep was equivalent to <1 mm of sediment deposition. The controlled laboratory data were compiled and evaluated to determine the sensitivity of the system. For each unit, we developed calibration curves to convert voltage into added wet weight using the wet weights calculated for the rubber sheets based on their air weight and volume. Wet weights were also converted to approximate dry weight values for sediment using an estimated density of sediment particles of 2.65 g/cm³, and subsequently to thicknesses using an estimated dry bulk density of 1.3 g/cm³. Standard deviations for each weight measurement were then compiled for wet weight, dry weight and thickness. Detection limits were then calculated from the formula

$$DL = T(0.99, n-1) \times SD$$

where T(0.99, n-1) is the T statistic and SD is the standard deviation. The resulting detection limits were averaged across the measured weights and then compared to the goal of sensitivity <1 mm.

Results for the laboratory detection limit testing are shown in Table 43. Testing of the original SeDep systems using the Omega sensors showed MDLs for thickness ranging from 0.008 to 0.014 mm with an overall average of 0.012 mm. This level of detection sensitivity was well below the success criteria. However, the sensors were found to have two issues during longer deployments in the field. First, the sensors had a tendency to drift, requiring weight tests before and after the deployment and detrending of the field results. Second, the sensors were found to corrode and several units became inoperable shortly after the first long field deployment. Based on these findings, an improved sensor (Validyne) was identified, tested, and incorporated into the system. Time constraints on the project limited the full integration and application of these new sensors. However

initial lab and field testing indicated that the primary issues with the original sensors were resolved. **Error! Reference source not found.** shows lab sensitivity testing results for one of these units which gave comparable sensitivity to the original sensors while also providing much improved stability and corrosion resistance. Overall, the success criteria for this performance objective was met.

6.8.2 Measurement Reliability

6.8.2.1 Description

The SeDep collects differential pressure data continuously at a rate of once every two seconds over periods of days to months. Often the goal is to identify trends or specific events. The data are subsequently transformed to sediment weight and thickness, and generally averaged to produce hourly or daily time series data for cumulative sediment deposition. For this reason, measurement reliability is important to assure that the data are sufficient to meet the goals of the study and capture the trends and events of interest.

6.8.2.2 Data Collection

Data for measurement reliability were obtained from differential pressure data during the field deployments in Pearl Harbor. These deployments lasted for approximately 42 days, and the data were recorded onboard the SeDep data logger and downloaded at the end of the deployment and used to examine measurement reliability.

6.8.2.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate reliable pressure data collected >90% of the deployment period. Data from the SeDep logger were first evaluated for data quality based on best professional judgement, and then compiled for each system. To determine the measurement reliability, the number of acceptable data values was then divided by the total number of data values for the deployment period. This value was then compared to the goal of reliable pressure data collected >90% of the deployment period.

Measurement reliability based on the field deployment in Pearl Harbor are summarized in Table 44. Reliability ranged from 87% to 100% for the ten units, with an overall average of 97%. Reliability less than 100% occurred for three units due to failure of the adhesive that was used to secure the pressure plate membrane. These failures generally occurred near the end of the deployment. The glued membranes have since been replaced with soldered stainless steel membranes to eliminate the problem. On the basis of these results, we concluded that the success criteria for the measurement reliability performance objective was met.

6.8.3 System survivability

6.8.3.1 Description

The SeDep units are designed to be deployed in harbor and coastal areas where exposure to harsh conditions is likely. The cost of performing the surveys can be significantly impacted if a large number of units are lost during the event. For these reasons, system survivability is an important metric for the SeDep systems.

6.8.3.2 Data Collection

System survivability data and statistics on successful mission completion, system failures, and lost units during field deployments were collected during the field deployments at Pearl Harbor. Data collected included the total number of systems deployed, the number that completed the mission successfully, the mode of system failure for those that didn't, the number of systems damaged during the deployment and the nature of the damage, and the number of systems lost during the deployment and the circumstances of the loss.

6.8.3.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate system survivability >80% under field conditions. Two different levels of survivability were evaluated including systems that were successfully retrieved but had significant damage (repair >50% of the system value), and systems that were completely lost or suffered complete loss damage (repair >100% of the system value). The difference between the number of deployed systems and the number of successful systems was divided by the number of deployed systems to calculate the success rate. The success rate was then compared to the performance objective.

Results for SeDep system survivability are summarized in Table 45. During and following the Pearl Harbor deployment, two issues occurred that impacted the system survivability performance. During the deployment period, the pressure plate membrane on three of the units (3,7 and 10) failed, leading to a loss of pressure difference signal. This failure was considered minor damage because replacement of the membrane is a relatively small cost as a percentage of the entire system (about 10%). As previously mentioned, the glued polycarbonate membranes were replaced with soldered stainless steel foil so that this problem should not occur in the future. After recovery, the units were tested and post-survey weight calibrations were performed successfully. However, about 5 weeks after the recover, it was discovered that five of the pressure sensors (1,3,4,6, and 9) had failed, apparently due to corrosion that had taken place inside of the sensing element. Based on these failures, combined with the sensor drift issue identified for the Omega sensors, we elected to replace the Omega sensors with an improved sensor from Validyne. To further reduce potential issues with corrosion, we also fully sealed the new sensors in polyurethane. Initial pier-side testing indicates that these improvements have successfully addressed the survivability and stability issues identified during the Pearl Harbor deployment, although long-term deployments are still needed to verify the robustness of the new configuration. Overall, the survivability success metric was not met, however, the issues that were identified have been addressed.

Table 43. Summary of results for the original SeDep deposition detection sensitivity.

| SeDep Unit | MDL (mV) | MDL Wet Wt (g) | MDL Dry Wt (g) | MDL Thick (mm) |
|-----------------|----------|----------------|----------------|----------------|
| SeDep1 | 1.78 | 0.77 | 0.46 | 0.009 |

6.9 Qualitative Performance Objectives – Sediment Deposition Detector

6.9.1 Ease of installation and retrieval

6.9.1.1 Description

The SeDep system provides a unique capability to monitor a continuous time series of sediment deposition at a fixed location while simultaneously capturing samples for subsequent physical and chemical analysis. A key aspect of the acceptance of the technology is that it be relatively easy to install and retrieve so that a reasonable number of samplers can be used to monitor the area of interest.

6.9.1.2 Data Collection

Data to assess the ease of installation and retrieval was collected based on field logsheets and feedback from the field and dive teams. Data from the logsheets was used to determine the time on station, number of stations per day, and any issues associated with the deployment or retrieval. Feedback from the field and dive teams was used to assess the ease or difficulty of the processes involved in the deployment and retrieval.

6.9.1.3 Interpretation of Data and Extent the Success Criteria Were Met

The goal for this performance objective was to demonstrate the ease of installation and retrieval for the SeDep system, and the ability to install or retrieve a typical system array within a reasonable time period of 1-2 days.

The ease of installation and retrieval was evaluated during the Pearl Harbor demonstration. During the deployment, we monitored time on station and the overall deployment rate. On-station times ranged from 5-30 minutes with an average of about 12 minutes. Including transit times for the boat, the overall deployment rate was about 10 stations in 4 hours or 2.5 stations/hour. The divers reported that the deployments were straightforward and the only difficulties that were encountered were deployment into an area containing coral rubble mixed with sediment that made it difficult to properly embed the SeDep unit into the bottom. Retrieval of the systems was also uneventful. The overall retrieval rate was 10 stations in less than 3 hours for a retrieval rate of about 3.3 stations/hour. Locating the units sometimes took the divers a couple of tries, but all ten units were successfully located and retrieved. Overall, the success criteria for the ease of installation and retrieval performance objective was met.

7 COST ASSESSMENT

The focus of the cost assessment element of the demonstration was to develop an understanding of the expected operational costs of the technologies. Considerations for the cost assessment including cost drivers, cost modeling, and the cost based are summarized below.

7.1 Cost Drivers

Cost drivers for the application of the technologies following implementation will largely be driven by capital equipment and maintenance costs, labor and overhead costs associated with the field work, logistics costs, consumables, analytical costs associated with the sampling elements, and labor and overhead costs associated with the data analysis and reporting. Based on knowledge of these cost elements, the overall costs of fielding and operating the technologies can be scaled depending on the specific nature and scope of the site and the project. Specific aspects of the cost drivers are described below.

7.2 Capital Equipment Costs

Capital costs for the equipment were developed based on data from the acquisition of the commercial prototype systems. These costs may vary in the future depending on evolution of the technology and the level of productions associated with demand for the technology. Estimated equipment costs for the three technologies are summarized below.

7.2.1 DrEx Equipment Costs

Commercial versions of the DrEx equipment are available from Brightwaters Instrument Company. Equipment cost estimates were made based on the ten units purchased for the demonstration. Actual costs may vary from these. The primary equipment costs include the drifter unit and the water sampler unit (Table 46). Other required items are a field computer and a field kit. Optional components include various sensors and lights. Incorporation of DGT passive samplers incurs no further costs. Incorporation of SPME samplers is still under development and costs are not available at this time. Other sensors and components can be incorporated for customization, but those costs are not considered here. Typical unit cost for the system as configured for the demonstration was \$5650 which included the drifter unit, the water sampler, the field computer, the field kit, and the Hobo temperature/conductivity sensor.

7.2.2 DPS Equipment Costs

Commercial versions of the DPS equipment are available from Pacific Gyre, Inc. Equipment cost estimates were made based on the ten units purchased for the demonstration. Actual costs may vary from these. The primary equipment cost is the drifter unit (Table 47). Other required items are a field computer and a field kit. Optional components include various sensors and lights, as well as the smaller shallow water drogues. Other sensors and components can be incorporated for customization, but those costs are not considered here. Typical unit cost for the system as configured for the

demonstration was \$9098 which included the drifter, the field computer, the field kit, the LED flasher, and the Hobo temperature/conductivity sensor.

7.2.3 SeDep Equipment Costs

Commercial versions of the SeDep equipment are not yet available from a commercial vendor. Equipment cost estimates were made based on the three units constructed after the demonstration that incorporated the improved pressure plate and pressure sensor. Actual costs may vary from these. The primary equipment costs include the pressure plate, the data logger, and the sediment trap (Table 48). Other required items are a field computer and a field kit. Optional components include various sensors. Other sensors and components can be incorporated for customization, but those costs are not considered here. Typical unit cost for the system as configured for the demonstration was \$3284 which included the pressure plate, the data logger, the sediment trap, the field computer, the field kit, and the TidBit temperature sensor.

Table 46. DrEx equipment costs.

| DrEx Component | Unit Cost | Notes |
|--|-----------|----------|
| Brightwaters Drifter Unit 121 | \$ 2,200 | Required |
| Brightwaters Water Sampler PAWS 127 | \$ 2,000 | Required |
| Field Computer | \$ 500 | Required |
| Field Kit/Tools | \$ 200 | Required |
| Brightwaters Temperature Sensor | \$ 75 | Optional |
| Brightwaters Temperature/Conductivity Sensor | \$ 1,200 | Optional |
| Brightwaters LED light | \$ 395 | Optional |
| Hobo Temperature/Conductivity Sensor | \$ 750 | Optional |
| Typical Unit Cost Per Demo Configuration | \$ 5,650 | |

Table 47. DPS equipment costs.

| DrEx Component | Unit Cost | Notes |
|--|-----------|----------|
| Pacific Gyre Sediment Tracker | \$ 7,538 | Required |
| Field Computer | \$ 500 | Required |
| Field Kit/Tools | \$ 200 | Required |
| Shallow Water Drogues | \$ 695 | Optional |
| Pacific Gyre Surface Temperature Sensor | \$ 100 | Optional |
| Pacific Gyre LED Solar Flasher | \$ 110 | Optional |
| Hobo Temperature/Conductivity Sensor | \$ 750 | Optional |
| Turbidity Sensor | \$ 1,500 | Optional |
| Typical Unit Cost Per Demo Configuration | \$ 9,098 | |

Table 48. SeDep equipment costs.

| SeDep Component | Unit Cost | Notes |
|--|-----------|----------|
| Pressure Plate With Validyne Sensor | \$ 1,583 | Required |
| MadgeTech Logger and Pressure Housing | \$ 779 | Required |
| Sediment Trap | \$ 89 | Required |
| Field Computer | \$ 500 | Required |
| Field Kit/Tools | \$ 200 | Required |
| TidBit Temperature Logger | \$ 133 | Optional |
| Hobo Temperature/Conductivity Sensor | \$ 750 | Optional |
| Turbidity Sensor | \$ 1,500 | Optional |
| Typical Unit Cost Per Demo Configuration | \$ 3,284 | |

7.3 Maintenance Costs

Maintenance costs for the equipment were developed based on experience during the field demonstrations. Maintenance costs encompass both routine servicing of the equipment, as well as repair and replacement associated with normal wear and potential damage and loss in the field. Estimated maintenance costs for the three technologies are summarized below.

7.3.1 DrEx Maintenance Costs

Maintenance for the DrEx system encompass both routine servicing of the equipment, as well as repair and replacement associated with normal wear and potential damage and loss in the field. Routine servicing generally includes cleaning, battery changes, limited repairs and storage. Major repair and replacement can include sails, sail rods, antennas, sensors, computer, drifter units, water sampler units, and complete systems. For estimating purposes, we assumed a maintenance rate of 10% of the capital costs per year. This equates to essentially complete replacement of each unit once every 10 years. Not including inflation, the estimated annual maintenance cost per unit is \$565.

7.3.2 DPS Maintenance Costs

Maintenance for the DrEx system encompass both routine servicing of the equipment, as well as repair and replacement associated with normal wear and potential damage and loss in the field. Routine servicing generally includes cleaning, battery changes, battery charging, limited repairs and storage. Major repair and replacement can include drogue sails, drogue hoops, sensors, computer, drifter units, winch units, and complete systems. For estimating purposes, we assumed a maintenance rate of 10% of the capital costs per year. This equates to essentially complete replacement of each unit once every 10 years. Not including inflation, the estimated annual maintenance cost per unit is \$910.

7.3.3 SeDep Maintenance Costs

Maintenance for the SeDep system encompass both routine servicing of the equipment, as well as repair and replacement associated with normal wear and potential damage and loss in the field. Routine servicing generally includes cleaning, battery changes, limited repairs and storage. Major repair and replacement can include pressure sensors, pressure

plates, fittings, electronics, cables, and complete systems. For estimating purposes, we assumed a maintenance rate of 10% of the capital costs per year. This equates to essentially complete replacement of each unit once every 10 years. Not including inflation, the estimated annual maintenance cost per unit is \$328.

7.4 Field Event Costs

Field event costs were developed based on experience during the field demonstrations. Field costs encompass labor costs for planning, mobilization, field operations, demobilization, analysis and reporting, and project management. Non labor costs typically include equipment, material and travel costs. Considerations for field costs for each of the technologies are summarized below.

7.4.1 DrEx Field Costs

Field costs for the DrEx system encompass labor costs for planning, mobilization, field operations, demobilization, analysis and reporting, and project management. Planning costs typically include study design, budgeting, contracting, sample plan development, and material orders. These tasks are generally assumed to be carried out by the principal scientist except material orders which are carried out by a technician. Mobilization costs can include equipment checkout, calibration, pre-cleaning, packing and shipping, which are generally carried out by a technician. Field operations include travel and return travel to the site, on-site setup and testing, the DrEx field survey, data downloads and quality control, and sample handling and shipping. These tasks are generally carried out by the field team which requires the principal scientist, 1-2 field technicians, and a boat captain. Demobilization includes post-cleaning, equipment breakdown, packing and shipping, which are carried out by the field team. Data analysis and reporting are generally carried out by the principal scientist. For labor cost estimates, typical burdened rates were assumed to be \$125/hr for the principal scientist, \$75/hr for the field technician(s), and \$75/hr for the boat captain. Labor costs are detailed in the cost modeling below.

Non labor costs for the DrEx system field operations typically include equipment, material and travel costs. Equipment costs include the DrEx units and ancillary equipment rentals, and the boat rental costs. Primary material items for a DrEx field survey include calibration standards, sample tubing, pump tubing, sampling bags/containers, batteries, log books/sheets, boat and vehicle fuel, Iridium satellite services, and DrEx composite sample analyses. There may be a small cost for disposal of investigation derived wastes associated with cleaning and decontamination of equipment. Travel costs generally include airfare, per diem, and vehicles. Costs for non-labor items are included in the cost modeling below.

7.4.2 DPS Field Costs

Field costs for the DPS system encompass labor costs for planning, mobilization, field operations, demobilization, analysis and reporting, and project management. Planning costs typically include study design, budgeting, contracting, sample plan development, and material orders. These tasks are generally assumed to be carried out by the principal scientist except material orders which are carried out by a technician. Mobilization costs can include equipment checkout, calibration, packing and shipping, which are generally

carried out by a technician. Field operations include travel and return travel to the site, on-site setup and testing, the DPS field survey, and data downloads and quality control. These tasks are generally carried out by the field team which requires the principal scientist, 1-2 field technicians, and a boat captain. Demobilization includes equipment breakdown, packing and shipping, which are carried out by the field team. Data analysis and reporting are generally carried out by the principal scientist. For labor cost estimates, typical burdened rates were assumed to be \$125/hr for the principal scientist, \$75/hr for the field technician(s), and \$75/hr for the boat captain.

Non labor costs for the DPS system field operations typically include equipment, material and travel costs. Equipment costs include the DPS units and ancillary equipment rentals, and the boat rental costs. Primary material items for a DPS field survey include calibration standards, batteries, log books/sheets, boat and vehicle fuel, and Iridium satellite services. Travel costs generally include airfare, per diem, and vehicles. Costs for non-labor items are included in the cost modeling below.

7.4.3 SeDep Field Costs

Field costs for the SeDep system encompass labor costs for planning, mobilization, field operations, demobilization, analysis and reporting, and project management. Planning costs typically include study design, budgeting, contracting, sample plan development, and material orders. These tasks are generally assumed to be carried out by the principal scientist except material orders which are carried out by a technician. Mobilization costs can include equipment checkout, calibration, pre-cleaning, packing and shipping, which are generally carried out by a technician. Field operations include travel and return travel to the site, on-site setup and testing, the SeDep field survey deployments, the SeDep field survey retrievals, data downloads and quality control, and sample handling and shipping. These tasks are generally carried out by the field team which requires the principal scientist, 1-2 field technicians, a boat captain, and a dive team. Demobilization includes post-cleaning, equipment breakdown, packing and shipping, which are carried out by the field team. Data analysis and reporting are generally carried out by the principal scientist. For labor cost estimates, typical burdened rates were assumed to be \$125/hr for the principal scientist, \$75/hr for the field technician(s), \$75/hr for the boat captain, and \$100/hr for divers (team of 2).

Non labor costs for the SeDep system field operations typically include equipment, material and travel costs. Equipment costs include the SeDep units and ancillary equipment rentals, boat rental costs, and dive gear rental costs. Primary material items for a SeDep field survey include batteries, log books/sheets, boat and vehicle fuel, Iridium satellite services, and sediment trap and surface sediment sample analyses. There may be a small cost for disposal of investigation derived wastes associated with cleaning and decontamination of equipment. Travel costs generally include airfare, per diem, and vehicles. Costs for non-labor items are included in the cost modeling below.

7.5 Cost Model

A cost model was developed for each of the technologies to estimate rental rates that would support capitalization of the equipment. It is expected that capital costs would be amortized over a fairly large number of site evaluations before the purchase of new

equipment would be required, and that these costs would be recouped through equipment rental fees passed on to the customer. These cost models are summarized below for each of the technologies.

7.5.1 DrEx Cost Model

The cost model for the DrEx system included the DrEx units and the main ancillary supporting equipment including the field kit, a field computer, and a temperature and conductivity sensor. Capital costs were estimated based on the data compiled in the equipment cost sections above. Future replacement costs were estimated assuming a 4% inflation rate. A range of rental rates were then estimated assuming a 10% annual maintenance rate, 3-15 uses (days) per year, and a 5-10 year service life (Table 49). The model results indicate required rental rates ranging from a low of \$58 per day for the high use and long service life scenario, to a high of \$497 per day for the low use, short service life scenario. For cost analysis purposes and based on our limited experience with the technology to date, we selected an intermediate rate of \$145 per day corresponding to 6 uses per year and a 10 year service life.

7.5.2 DPS Cost Model

The cost model for the DPS system included the DPS units and the main ancillary supporting equipment including the field kit, a field computer, and a temperature and conductivity sensor. Capital costs were estimated based on the data compiled in the equipment cost sections above. Future replacement costs were estimated assuming a 4% inflation rate. A range of rental rates were then estimated assuming a 10% annual maintenance rate, 3-15 uses (days) per year, and a 5-10 year service life (Table 50). The model results indicate required rental rates ranging from a low of \$93 per day for the high use and long service life scenario, to a high of \$800 per day for the low use, short service life scenario. For cost analysis purposes and based on our limited experience with the technology to date, we selected an intermediate rate of \$233 per day corresponding to 6 uses per year and a 10 year service life.

7.5.3 SeDep Cost Model

The cost model for the SeDep system included the SeDep units and the main ancillary supporting equipment including the field kit, a field computer, and a temperature sensor. Capital costs were estimated based on the data compiled in the equipment cost sections above. Future replacement costs were estimated assuming a 4% inflation rate. A range of rental rates were then estimated assuming a 10% annual maintenance rate, 30-150 uses (days) per year, and a 5-10 year service life (Table 51). The model results indicate required rental rates ranging from a low of \$3 per day for the high use and long service life scenario, to a high of \$29 per day for the low use, short service life scenario. For cost analysis purposes and based on our limited experience with the technology to date, we selected an intermediate rate of \$14 per day corresponding to 60 uses per year and a 5 year service life.

7.6 Cost Analysis

A cost analysis for each of the technologies was performed based on the assumptions and models summarized in the previous sections. The cost analysis was performed for each of the technologies independently, however it should be recognized that in actual applications they may be combined in various configurations, and that there are likely to be cost efficiencies associated with this in terms of reductions in mobilization and logistical costs. For each system, a range of different scales of application was assessed to provide insight into the potential costs associated with implementation at different sites.

7.6.1 DrEx Cost Analysis

The cost analysis for the DrEx system focused on application scenarios in which the system is deployed at one or more stormwater outfalls and used for plume tracking and exposure measurements over short periods of time. We analyzed costs for three application scenarios (Table 52). The small-scale application assumed the release of five DrEx units during first flush at a single outfall and tracking for a period of 12 hours. The mid-scale scenario assumed the release of five DrEx units during first flush at each of two outfalls and tracking for a period of 12 hours. The large-scale scenario assumed the release of five DrEx units during first flush at each of five outfalls and tracking for a period of 12 hours. All scenarios assumed samples would be collected for each unit that was released and that samples would be analyzed for TSS, metals and organics. All events included temperature and conductivity sensors as well.

Results for the cost analysis are shown in Table 53 – Table 55. Overall application costs ranged from a low of \$42089 for the small-scale application (one outfall) to \$125466 for the large-scale application (five outfalls). There is some efficiency of scale as the costs of large applications are lower than just a linear scaling based on the number of outfalls. This appears to results from improved efficiencies in the labor costs for most categories (Figure 130). A significant cost driver for scale up is the analytical costs associated with the DrEx composite sample analysis. Overall, the largest components of the application cost tend to be the field operations and materials costs (15-30%), followed by planning and analysis and reporting costs (10-15%).

Table 52. Scaling parameters for the three DrEx application scenarios.

| Cost Parameter | Small Scale | Mid Scale | Large Scale |
|-------------------------------------|---------------------------|---------------------------|---------------------------|
| Outfalls | 1 | 2 | 5 |
| DrEx Units (per outfall) | 5 | 5 | 5 |

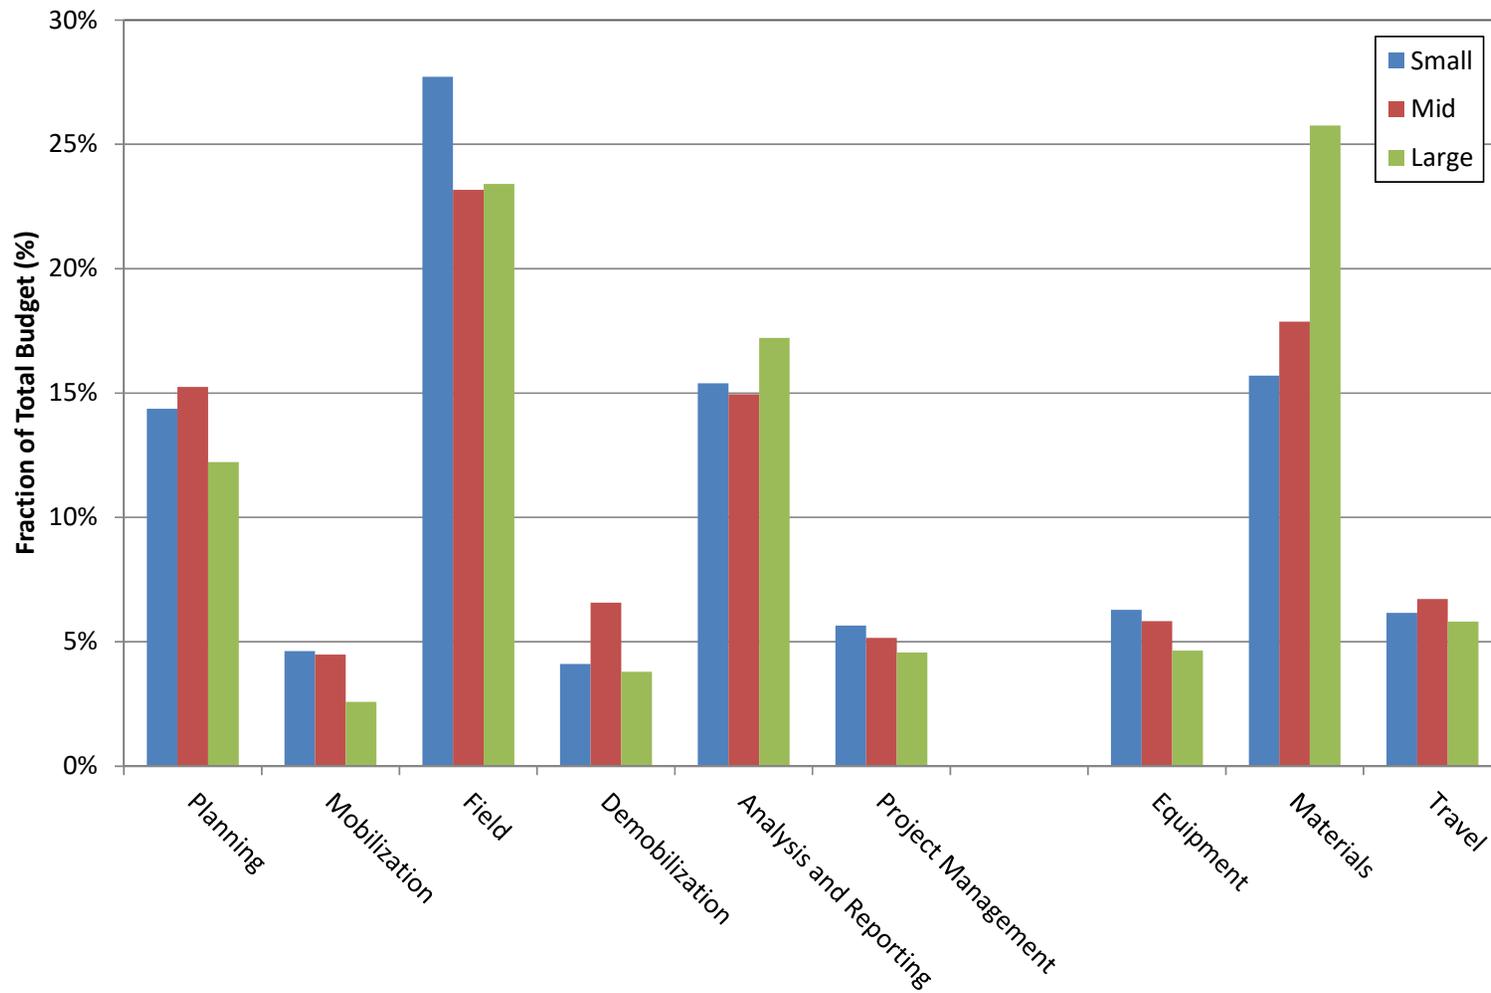

Figure 130. Cost element fraction of the total application budgets for DrEx technology at three scales.

7.6.2 DPS Cost Analysis

The cost analysis for the DPS system focused on application scenarios in which the system is deployed at one or more stormwater outfalls and used for determining the associated deposition footprint that is connectivity with the outfall(s) over typical tidal or other relevant short-term periods of variability. We analyzed costs for three application scenarios (Table 56). The small-scale application assumed the release of five DPS units at a single outfall location repeatedly through an entire 24-hour tidal cycle period. The mid-scale application assumed the release of five DPS units at each of two outfall locations repeatedly through an entire 24-hour tidal cycle period. The large-scale application assumed the release of five DPS units at each of five outfall locations repeatedly through an entire 24-hour tidal cycle period. All scenarios included temperature and conductivity sensors as well.

Results for the cost analysis are shown in Table 57 – Table 59. Overall application costs ranged from a low of \$36995 for the small-scale application (one outfall) to \$115935 for the large-scale application (five outfalls). There is some efficiency of scale as the costs of large applications are lower than just a linear scaling based on the number of outfalls. This appears to results from improved efficiencies in the labor costs for most categories. A significant cost driver for scale up is the equipment costs associated with the higher use of DPS units and their relatively high rental rates (Figure 131). Overall, the largest component of the application cost tends to be the field operations (25-30%), followed by planning costs, analysis and reporting costs and equipment costs (10-20%).

Table 56. Scaling parameters for the three DPS application scenarios.

| Cost Parameter | Small Scale | Mid Scale | Large Scale |
|-------------------------|---------------------------|---------------------------|---------------------------|

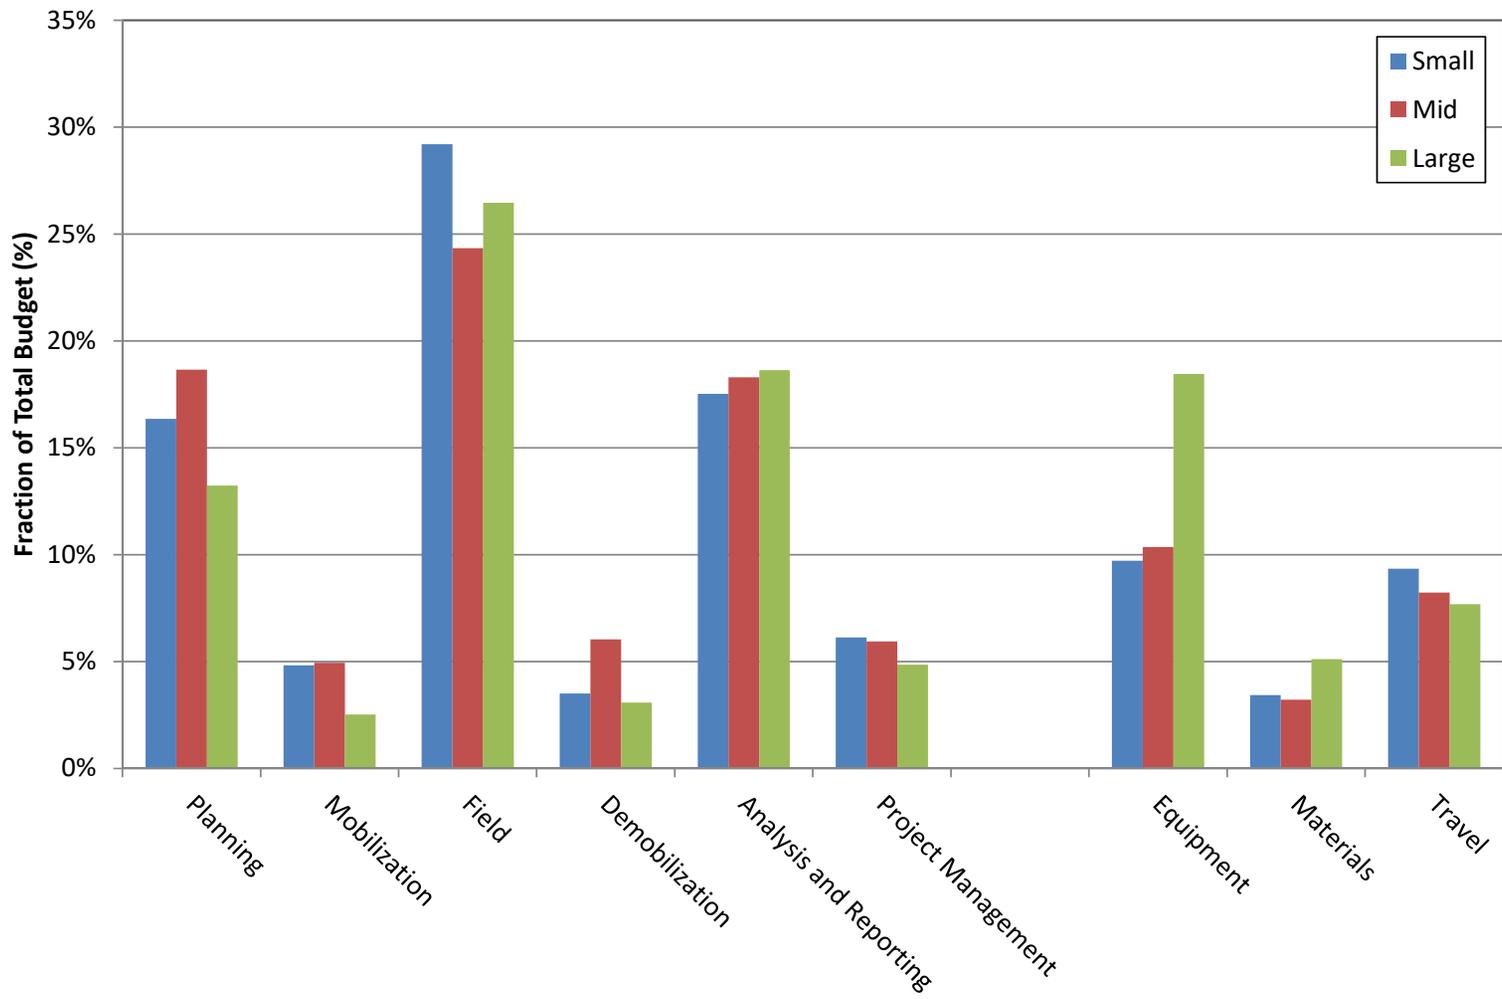

Figure 131. Cost element fraction of the total application budgets for DPS technology at three scales.

7.6.3 SeDep Cost Analysis

The cost analysis for the SeDep system focused on application scenarios in which the system is deployed at one or more stormwater outfalls and used for determining the associated deposition rates, mass loading, and chemical loading associated with particle deposition in the area. We analyzed costs for three application scenarios (Table 60). The small-scale application assumed the deployment and retrieval of five SeDep units at a single outfall location over a 30 day period. The mid-scale application assumed the deployment and retrieval of five SeDep units at each of two outfall locations over a 30 day period. The large-scale application assumed the deployment and retrieval of five SeDep units at each of five outfall locations over a 30 day period. All scenarios included sediment trap samples, surface sediment samples, and temperature sensors.

Results for the cost analysis are shown in Table 61 – Table 63. Overall application costs ranged from a low of \$58422 for the small-scale application (one outfall) to \$211909 for the large-scale application (five outfalls). Overall, the largest component of the application cost tends to be the field operations (30-35%), followed by material costs (20-25%). The relatively high field costs are driven by requirements for diver deployment and recovery of the equipment, while the material costs are driven primarily by analytical costs for the sediment trap and surface sediment samples(Figure 132).

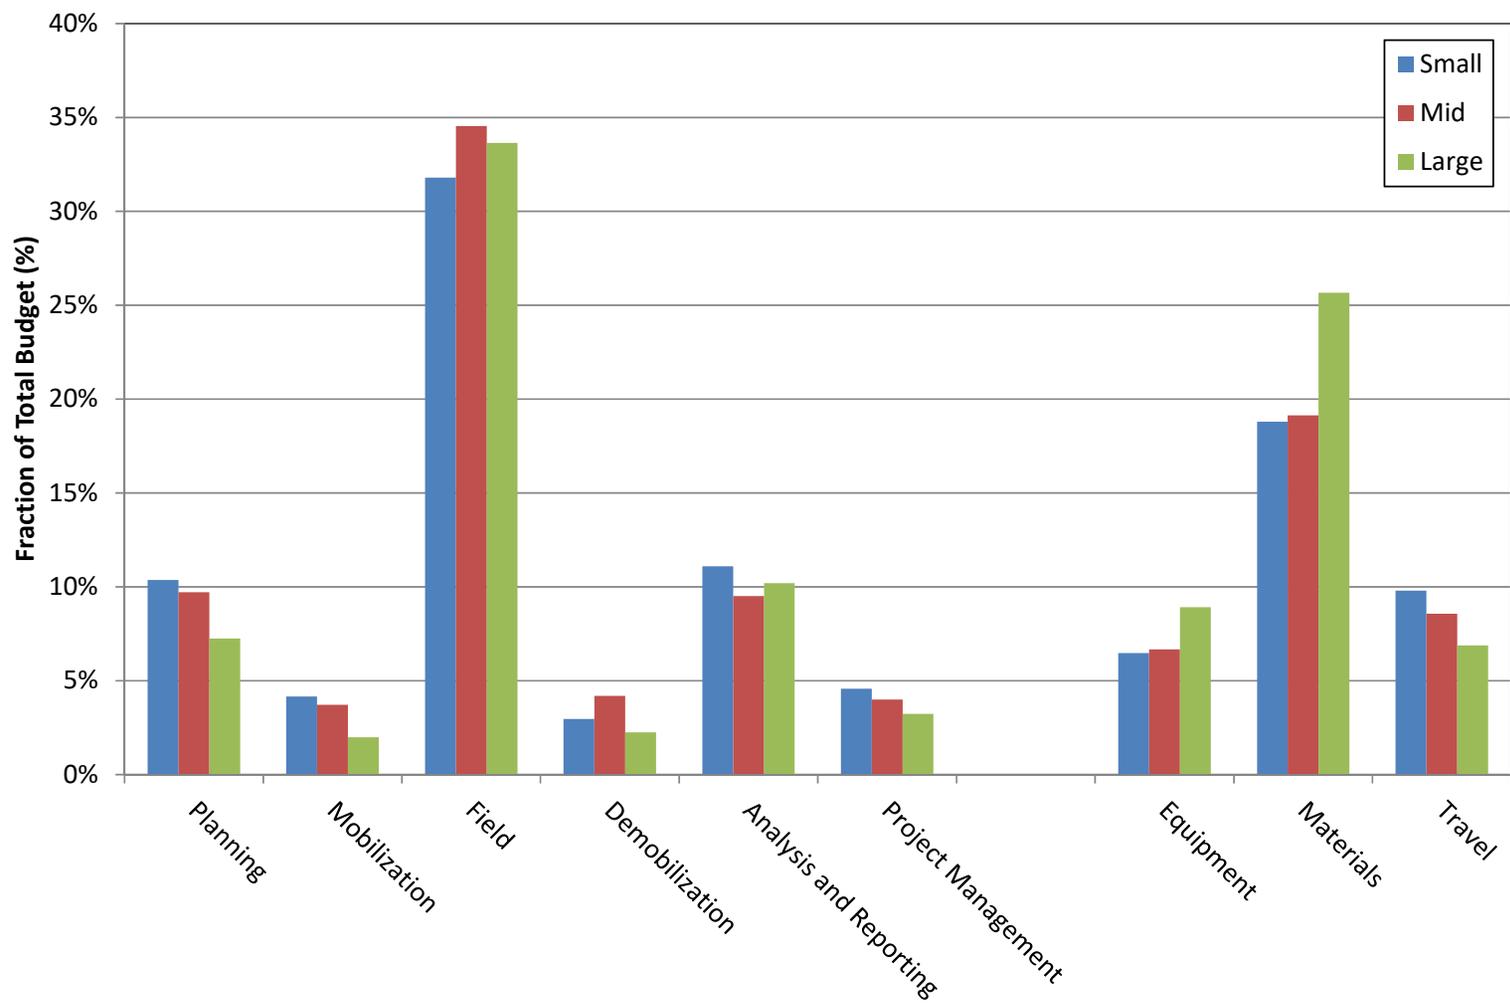

Figure 132. Cost element fraction of the total application budgets for SeDep technology at three scales.

7.7 Cost Summary

The focus of these technology demonstrations was on the evaluation of new capabilities that expand the tool box for assessing stormwater and sediment recontamination beyond what is currently available. Thus the cost analysis focused on providing a good definition of the costs associated with implementation over a range of scales. Overall it appears that the costs associated with the technologies is within the range of typical field survey events for other aspects of sediment assessment and characterization. Assuming that the technologies would be incorporated and applied with other traditional characterization phases of a remedial investigation or stormwater monitoring program, significant efficiencies in costs could be expected.

This page intentionally left blank

8 IMPLEMENTATION ISSUES

Through our experience with a large number of demonstration projects, we have developed an over-arching strategy for implementation based on several key components including:

- The technology is well demonstrated and documented
- Standard operating procedures are developed and available
- Equipment is available on the open market
- Technology service providers are available to DoD users
- Regulators have visibility of the technology

To the extent possible, we have attempted to make progress on each of these components through the course of this project. This progress is summarized below along with remaining gaps and lessons learned during the field demonstrations.

8.1 Technology Demonstration

The DrEx technology has undergone limited demonstration at one site for two storm events. These demonstrations have provided a high level of confidence that the technology can achieve the defined objectives of tracking and sampling stormwater plumes to better define potential for exposure and recontamination. Technical issues identified during these field events have been corrected. Logistical challenges associated with working in and around an active DoD facility were found to be manageable. The demonstrations were well documented through the ESTCP Site Selection Memorandum, Demonstration Plan, and this Technical Report, as well as through a series of conference presentations and publications. The technology would still benefit from further demonstration by early adopters under a broader range of facilities, discharge conditions, environmental settings, and regulatory applications.

The DPS technology has undergone limited demonstration at one site for two deposition mapping events. These demonstrations have provided a high level of confidence that the technology can achieve the defined objectives of tracking particle trajectories and mapping deposition footprints for potential recontamination associated with particle releases from specific outfalls. Technical issues identified during these field events have been corrected. Logistical challenges associated with working in and around an active DoD facility were found to be manageable. The demonstrations were well documented through the ESTCP Site Selection Memorandum, Demonstration Plan, and this Technical Report, as well as through a series of conference presentations and publications. As with the DrEx system, the DPS technology would still benefit from further demonstration by early adopters under a broader range of facilities, discharge conditions, environmental settings, and regulatory applications.

The SeDep technology has undergone limited demonstration at one site for one extended monitoring event. This demonstration provided a moderate level of confidence that the technology can achieve the defined objectives of monitoring and sampling deposition in areas of interest to characterize recontamination potential. Technical issues identified during these field events have been corrected, but there has been limited testing of the system following those improvements. Logistical challenges associated with working in and around an active DoD facility were found to be manageable. The demonstration was well documented through the ESTCP Site Selection Memorandum, Demonstration Plan, and this Technical Report, as well as

through a series of conference presentations and publications. The SeDep technology would benefit from more rigorous testing and demonstration prior to use by early adopters. However, direct transition to users is also possible, but would likely require some investment by the service provider to assure that the new systems will perform as expected under a range of application conditions.

8.2 Standard Operating Procedures

Standard operating procedures have been developed for all of the technologies. These are well documented in manuals provided by the equipment companies, as well as in the procedural documents contained in the ESTCP Demonstration Plan. It is expected that these procedures could be refined and improved over time based on experience, and that this would help to improve the implementation process and potentially reduce the application costs.

8.3 Equipment Availability

The DrEx equipment is all currently available from the vendors described in this document. Similarly, the DPS equipment is fully available from the commercial vendor that participated in the project. For the SeDep system, we were unable to finalize a relationship with a commercial vendor, although the systems are based directly on the commercially available system. We believe the improvements that were incorporated into the SeDep system are essential to improving the performance to the level where it can meet the objectives specified for the technology, particularly with respect to sensitivity and operation in deeper water. The SeDep technology would benefit from further effort toward commercialization to ensure the equipment would be widely available.

8.4 Service Providers

During the equipment development and demonstration, we had ongoing collaboration with potential technology service providers. Our primary partner as a service provider on the project was with Ramboll and Geosyntec Consultants who supported various aspects of the development, testing and demonstration of the technology. These consultants would be well positioned to support the technologies as service providers in the future. In addition, the technologies are suitably documented and straightforward enough that any experienced environmental consulting company could provide the required support after a relatively short learning curve. The DrEx and DPS technologies are currently in patent pending status, and there may be future opportunities for service providers to license the technology. Implementation of the technology would be well served by having the technology be picked up and promoted by a commercial consulting firm for future applications at DoD sites.

8.5 Regulatory Visibility

To date the technologies have had some limited regulatory exposure. The technology was briefed and toured to staff from the San Diego Regional Water Quality Control Board during the period of the demonstrations in San Diego Bay. Results from the demonstrations in Pearl Harbor have also been briefed to the regulatory team associated with the Pearl Harbor sediment cleanup. The RPM at Pearl Harbor has been actively involved in the project and in implementing the technology at her site, and represents a key early adopter for the technology. The technology

would benefit from further exposure to regulatory agencies that have oversight over stormwater and/or sediment cleanups.

8.6 Lessons Learned

Important lessons that can help to inform future implementation were learned during the field demonstrations for the three technologies. These are summarized below for each of the three technologies.

8.6.1 Drifting Exposure System

Beyond the specific quantitative and qualitative performance assessment metrics describe previously, there were a number of practical lessons learned during the field demonstrations for the DrEx system. One key aspect was the need to have a flexible protocol for when to release the units during the storm. In our demonstrations, we focused on release during first-flush, but storms do not always cooperate both in terms of timing of the event and the hydrograph of the event. Low levels of precipitation may go on for some time with low discharge flows, and high flows that constitute a clear first-flush event may be sporadic or come later in the event. One way to address this that we utilized was to monitor the salinity of the surface water adjacent to the outfall and only release the units when we saw a clear influence of stormwater in the surface waters.

Another practical consideration was the time required to setup and deploy the units. We did not have sufficient deck space to have all of the units fully assembled and ready to go for the release, and final setup took several minutes for each unit. Given that there were 10 units, this consumed a significant amount of time and precipitation and flow conditions varied over this period. Ideally, the units would be setup and ready to go. One consideration for this is the question of how many units are really required to assess the trajectory and exposure levels in the plume. For smaller outfalls, it seems like a reduced number of units would suffice, while for larger discharges like the urban creek that we studied, it was helpful to have the larger number of units. For future implementation, these design factors should be weighed in terms of practicality versus data requirements.

Regarding the robustness of the DrEx units, we were generally pretty happy with how they held up under some pretty challenging conditions. However, there is still significant room for improvement in the design and engineering of the systems. Their current design and construction is based on standard PVC pipe and pipe fittings. This is attractive from the standpoint of cost and replacement parts, but results in a relatively bulky and non-optimal design. We had some problems with the electronics shifting within the housings, failure of water seals, breakage of sensor brackets and wear of drogue sails. As previously discussed, the sampling bags also could use improvement. For future implementation, it might be advisable to re-design the system with purpose-built components and materials that are specifically engineered for the anticipated ruggedness of the near-shore application in harbor areas where the units are likely to come in physical contact with piers and other hard structures under stormy conditions with significant wind and wave action.

From the perspective utility to the site manager, the technology provides a new and unique capability for providing both visual and quantitative data to support future controls and permit applications in the stormwater regulatory realm, and source characterization in the cleanup

realm. In the stormwater context, rigorous, defensible data that can demonstrate whether or not there are direct effects related to stormwater exposure in the receiving system, combined with an understanding of the magnitude and spatial extent of exposure are strong lines of evidence for the site manager to support either the required expenditures to implement controls, or to support the argument that the discharge does not represent a risk to the environment. This ability to help focus resources on areas where they are truly needed is generally lacking in current-day stormwater programs. From the cleanup perspective, site managers are struggling to determine if ongoing sources such as stormwater represent a potential threat to sediment remediation. The DrEx system provides a unique ability for direct measurement of the trajectories and contaminant levels associated with stormwater plumes. Combined with the other technologies demonstrated here, these tools can certainly help to reduce the uncertainties associated with making decisions on whether and when to implement expensive sediment remedies.

8.6.2 Drifting Particle Simulator System

As with the DrEx system, there were a number of practical lessons learned during the field demonstrations for the DPS system. One key consideration is having a good initial estimate of the distance that the units will travel prior to bottom contact. In the Oscar Pier demonstration, the systems traveled further than expected which led to additional logistical considerations for working in areas of the harbor that we had not anticipated. Depending on the available data for current speeds in the area, a reasonable estimate of the travel distance can be made using the current speed, water depth and programmed settling rate. These calculations could be incorporated into a simple spreadsheet-based planning tool as part of the pre-deployment checklist.

Another useful tool that could be incorporated into the tracking software would be a projection of the units position based on previous measurements. Because the position reports are several minutes apart, the DPS can travel some distance between reports, and under night time or low visibility conditions the system can be difficult to find. Alternatively, the satellite link could be used to query the current location of the unit by sending it a command.

Regarding the robustness and reliability of the DPS system, we were very happy with the overall performance. The systems are purpose-built and performed very reliably, generally exceeding our expectations given the somewhat complex nature of the hardware. One design flaw that led to a system failure was the ability for water to enter the winch unit when the dummy plug is not in place on the underwater connection. This is due to the fact that the battery vents through this port when charging, so there needs to be a clear path. Some fail-safe method to assure that this port is sealed prior to deployment would help to avoid a costly system flooding event.

From the perspective utility to the site manager, the technology provides a new and unique capability for linking specific discharge locations to their associated deposition footprint for particle releases. To our knowledge, this is the only direct measurement technique other than tracer particles that can provide this information. Given the high costs, environmental concerns, tracking challenges and one time nature of particle tracking methods, the DPS unit provides an effective alternative. The deployment at Waiiau provided direct support to an emerging, site-specific source tracking question and illustrates the ability of the system to directly address these types of questions.

8.6.3 Sediment Deposition Detector System

Lessons learned during the field demonstrations for the SeDep system centered on how to improve the reliability of the system over long-term deployments. Problems with both the pressure plate and the pressure sensors following long-term exposure to the underwater environment led to system failure for many of the units following the Oscar Pier demonstration. We made significant improvements to the system based on these lessons learned including:

- Return to use of a soldered stainless steel foil membrane for the pressure plate
- Development of a reliable soldering method for applying the membranes to the pressure plate pan
- Identification of a more reliable pressure sensor
- Development of a robust waterproofing method for the pressure sensors

Lab calibrations and pier-side testing following the incorporation of these improvements indicated that they have significantly improved both the performance and the reliability of the system. Unfortunately we did not have adequate time or resources to pursue an additional field demonstration prior to the culmination of the project.

From the perspective utility to the site manager, the technology provides a new and unique capability for measuring the time-series of sediment deposition and/or erosion at a fixed location at the sediment bed. Traditional methods such as sediment traps only provide a net deposition over the deployment period and thus lack any information on the timing or processes involved in the sedimentation. All sediment remedies are sensitive to the deposition of new sediment. Remedies such as monitored natural recovery (MNR) and enhanced monitored natural recovery (EMNR) generally rely on deposition of clean material to achieve their goals. Remedies such as capping and dredging are sensitive to new deposition from both a recontamination perspective and in terms of potential impacts to navigation depths. Having a quantitative means to measure these rates and link them to specific processes, events or activities will help to reduce the uncertainties associated with implementation of these remedies.
